(Dated: March 1, 2012)

The competition between intertube hopping processes and density-density interactions is investigated in one-dimensional quantum dipolar bosons systems of N coupled tubes at zero temperature. Using a phenomenological bosonization approach, we show that the resulting competition leads to an exotic quantum phase transition described by a U(1) $\times$ $\mathbb{Z}_N$ conformal field theory with a fractional central charge. The emerging $\mathbb{Z}_N$ parafermionic critical degrees of freedom are highly nontrivial in terms of the original atoms or polar molecules of the model. We further determine the main physical properties of the quantum critical point in a double-tube system which has central charge $c = 3/2$. In triple-tube systems, we show that the competition between the two antagonistic processes is related to the physics of the two-dimensional $\mathbb{Z}_3$ chiral Potts model. This work opens the possibility to study the exotic properties of the $\mathbb{Z}_N$ parafermions in the context of ultracold quantum Bose gases.

I. INTRODUCTION

Ultracold atomic systems have become one of the most experimentally flexible systems to study strongly correlated physics. The possibility of tuning the contact inter-particle interactions by varying the scattering length through Feshbach resonances has allowed the observation of many interesting phenomena like the BEC-BCS crossover in atomic Fermi gas.[1]

On top of this wide tunability of the interaction strength, the possibility of controlling the shape of interactions through the long-range and anisotropic nature of dipole-dipole interactions has recently attracted considerable attention. In particular, dipolar interactions with long-range anisotropic character have been observed in chromium atoms by exploiting its large magnetic moments.[2] An alternative route is to consider heteronuclear polar molecules with large electric dipole moments associated with their rotational excitations.[3,4] The resulting long-range interactions between such polar molecules can be tuned using dc and ac electric fields.[5,6] Dipole-dipole interactions can then be much stronger than the superexchange interactions between ultracold atoms. This opens an avenue to realize a plethora of interesting quantum phases governed by long-range interactions. On the one hand, a variety of exotic phases have already been predicted to occur in dipolar quantum gases such as topological p-wave fermionic superfluids[7] and quantum nematic fluids.[8,9] On the other hand, as shown recently in Ref.10, ultracold polar molecules become promising candidates for the simulation of condensed matter phenomena and could provide a robust toolbox for quantum information processing.

In this paper, we investigate the emergence of an exotic quantum criticality in coupled one-dimensional (1D) quantum bosons tubes with dipole-dipole interactions. The standard quantum critical behavior of 1D quantum bosons is the well-known Luttinger universality class.[11–14] Its low-energy properties are governed by a relativistic free massless boson field Φ with a sound velocity v and a Luttinger parameter K which depend on the density and interactions of the underlying 1D quantum Bose gas. A hallmark of the Luttinger phenomenology is the power-law decay of the physical quantities with non-universal exponents related to the Luttinger parameter K. Such universality class can in turn be viewed as a conformal field theory (CFT) with U(1) global continuous symmetry and central charge $c = 1$ associated to the gapless free-bosonic mode Φ.[15,16] A more complicate quantum-critical behavior has been found recently with ultracold bosons with the possible realization of the 2D Ising universality class.[17–21] In that case, the criticality emerges at a quantum critical point characterized by a $\mathbb{Z}_2$ CFT with central charge $c = 1/2$. The resulting gapless degree of freedom is a free massless Majorana (real) fermion which is half of a Dirac (complex) fermion.[15,16] Here, in the context of coupled 1D dipolar bosons, we analyse the stabilization of exotic quantum critical points which are described by the SU(2)$_N$ CFT with central charge $c = 3N/(N + 2)$.[22] Equivalently, the emergent quantum criticality can be captured by the product of a conventional U(1) CFT with the $\mathbb{Z}_N$ parafermions CFT, with central charge $c = 2(N - 1)/(N + 2)$, which is known to govern the critical properties of the 2D $\mathbb{Z}_N$ generalization Ising models.[23,24] Such nontrivial quantum criticality for $N > 2$ cannot be described by a simple free-field theory in terms of 1D gapless bosons or fermions as it is the case for the Luttinger and Ising universality classes. In this respect, the resulting critical degrees of freedom are highly nonlocal with respect to the original atoms or molecules. Recently, the $\mathbb{Z}_N$ parafermions CFT has attracted a lot of interest in the context of non-Abelian fractional quantum Hall states. The so-called Read-Rezayi states are described in terms of the $\mathbb{Z}_N$ CFT and their excitations display non-Abelian statistics which stem from the parafermionic behavior of these states.[25] Our work opens the possible realization of this exotic CFT with fractional central charge in the context of ultracold atoms or polar molecules.

The experimental setup that allows to create a system of coupled 1D dipolar bosons tubes, is similar to the one de-

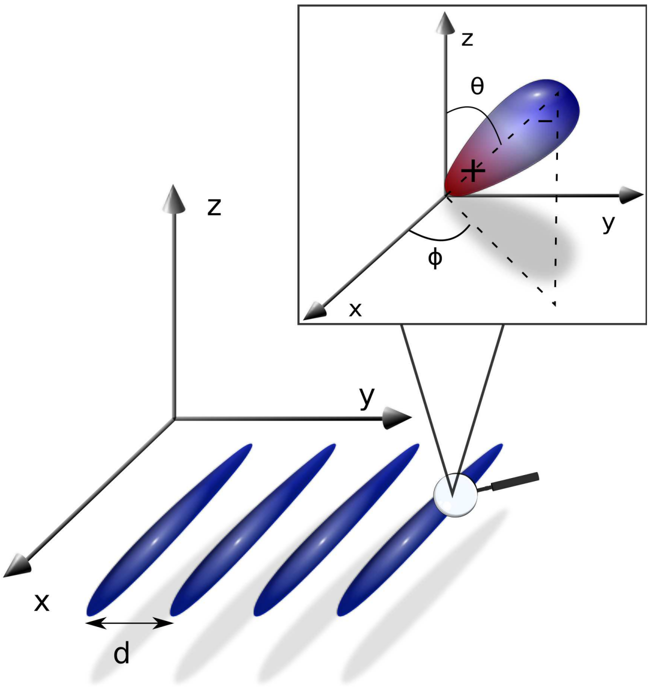

FIG. 1: (color online) Planar array of 1D tubes of dipolar boson gas positioned along the x axis. The dipoles are all aligned along an additional external field.

scribed in Refs.26–30. A planar array of 1D tubes of dipolar boson gas, as shown in Fig. 1, is formed by an anisotropic 2D optical lattice in the $z-y$ plane. The strong confinement in the z-direction completely suppresses the hopping in that direction, while we allow a weak hopping between the tubes along the y-direction. Neglecting the inhomogeneity of the trapping potential, the system is thus a stack of 2D arrays, containing identical (straight) tubes of bosons, all oriented along the x-axis and separated by a distance $d=\lambda/2$ in the y-direction (λ being the wavelength of the laser) . The dipole moments of the bosons are aligned by an additional external field which is electric in the case of polar molecules or magnetic for chromium atoms. The dipole-dipole interaction strength can be tuned by using a rotating field, which induces a precession of the dipoles around the z-axis.[2,31]

The resulting effective Hamiltonian for this system can be written as:

$$\mathcal{H}=\mathcal{H}_{\text{intra}}+\mathcal{H}_{\text{inter}}. \tag{1}$$

$\mathcal{H}_{\text{intra}}$ is the Hamiltonian describing the bosons' motion and interactions within the same tube:

$$\mathcal{H}_{\text{intra}}=\sum_{n=1}^{N}\int dx\ \Psi_n^\dagger(x)\,(-\frac{\hbar^2}{2M}\frac{d^2}{dx^2})\Psi_n(x)$$
$$+\sum_{n=1}^{N}\int dx_1dx_2\ V_{dd}^{\text{intra}}(x_1-x_2)\,\rho_n(x_1)\,\rho_n(x_2)\,, \tag{2}$$

where $\Psi_n^\dagger(x)$ is the bosonic operator that creates a dipole at position x in tube n, and $\rho_n(x)=\Psi_n^\dagger(x)\Psi_n(x)$ is the density operator. In Eq. (2), M is the mass of the bosons and V_{dd}^{intra} denotes the intratube dipole-dipole interaction. The coupling between the tubes is composed of the hopping along the y direction, with amplitude $J_\perp$, and the intertube dipole-dipole interactions described by V_{dd}^{inter}:

$$\mathcal{H}_{\text{inter}}=-J_\perp\sum_{n=1}^{N-1}\int dx\left[\Psi_n^\dagger(x)\,\Psi_{n+1}(x)+H.c.\right]$$
$$+\sum_{n=1}^{N-1}\int dx_1dx_2\ V_{dd}^{\text{inter}}(x_1-x_2)\,\rho_n(x_1)\,\rho_{n+1}(x_2)\,. \tag{3}$$

Here, we only consider coupling between nearest-neighbor tubes as in Ref.26. Unless stated otherwise (in Sec. IV), open-boundary conditions in the transverse direction (y) are also assumed in Eq. (3). The two terms in Eq. (3) are of very different nature and can be tuned independently: the depth of the optical lattice potential in the y direction controls the inter-tube hopping amplitude $J_\perp$, while V_{dd}^{inter} is controlled by the rotating polarizing field.

In this paper, we will investigate the competition between these two sources of coupling, at zero temperature, and in the 1D regime where the total length in the transverse direction, i.e. Nd, is finite. In this respect, small values of N, i.e. $N=2$ or 3, can be obtained in principle, by selective evaporation of the tubes by using electric or magnetic field gradients. Alternatively, double-tube system can also be engineered by considering double-well optical lattices.[32]

The rest of the paper is organized as follows. In Sec. II, we follow a low-energy approach for the model (1) in the general N case, using the phenomenological bosonization of the bosons[11–14] supplemented by CFT techniques. There, we reveal the existence of a quantum critical point in the SU(2)$_N$ universality class, which describes the competition between hopping and intertube interactions. The properties of this fixed point and its stability with respect to general perturbations are further analysed in the special cases $N=2,3$ in Sec. III and IV. In particular, we show that the low-energy properties of triple-tube systems are related to the physics of the $\mathbb{Z}_3$ chiral Potts model.[33] Finally, Sec. V contains our concluding remarks. The paper is supplied with an Appendix which provides some important technical details.

II. QUANTUM PHASE TRANSITION IN THE GENERAL N TUBE CASE

In this section, we will investigate the nature of the quantum phase transition which stems from the competition between the hopping term and the intertube density-density interaction of Eq. (3) in the general N case.

A. Phenomenological bosonization approach

Let us first specify the form of the dipole-dipole interactions which appear in Eqs. (2, 3). The dipole moments are polarized along a direction $\mathbf{d}=(\sin\theta\cos\phi,\sin\theta\sin\phi,\cos\theta)$ in the spherical coordinates (see Fig. 1). The energy due to the interaction between two dipoles at relative position $\mathbf{r}$ is:

$$V_{\mathrm{dd}}\left(\mathbf{r}\right)=\frac{C_{dd}}{4\pi}\frac{r^{2}-3\left(\mathbf{d}\cdot\mathbf{r}\right)^{2}}{r^{5}},\tag{4}$$

where the coupling constant is $C_{dd}=p^{2}/\epsilon_{0}$ for electric dipoles of strength p, and $C_{dd}=\mu_{0}\mu^{2}$ for magnetic dipoles of strength μ; ϵ_{0} and μ_{0} are respectively the vacuum permittivity and permeability. For two dipoles in the same tube, the dipole-dipole interaction is then:

$$V_{\mathrm{dd}}^{\mathrm{intra}}\left(x_{1}-x_{2}\right)=\frac{C_{dd}}{4\pi}\frac{1-3\sin^{2}\theta\cos^{2}\phi}{\left|x_{1}-x_{2}\right|^{3}}.\tag{5}$$

It may be convenient to fix θ to its magic angle value: $\sin\theta=1/\sqrt{3}$ in order to get repulsive interactions. Within this hypothesis, as in Ref.26, we approximate the dipole-dipole interaction between two nearest-neighbor tubes by its leading contribution:

$$V_{\mathrm{dd}}^{\mathrm{inter}}\left(x_{1}-x_{2}\right)\simeq\frac{C_{dd}}{4\pi}\frac{\cos^{2}\phi}{d^{3}}\delta\left(x_{1}-x_{2}\right).\tag{6}$$

As we will show thereafter, repulsive intertube dipole-dipole interactions are not crucial for the existence of the quantum phase transition we investigate. Thus, without loss of generality regarding the nature of the intertube interactions, we will choose $\theta=\phi=\pi/2$, i.e. the dipoles are polarized along the y-axis, perpendicular to the tubes axis; we then have a short-distance intertube attraction

$$V_{\mathrm{dd}}^{\mathrm{inter}}\left(x_{1}-x_{2}\right)\simeq-\frac{C_{dd}}{2\pi d^{3}}\delta\left(x_{1}-x_{2}\right),\tag{7}$$

and a repulsive intratube interaction:

$$V_{\mathrm{dd}}^{\mathrm{intra}}\left(x_{1}-x_{2}\right)=\frac{C_{dd}}{4\pi}\frac{1}{\left|x_{1}-x_{2}\right|^{3}}.\tag{8}$$

With these specifications, we are now in position to investigate the physical properties of model (1) by means of the phenomenological bosonization (or harmonic-fluid approach). It is a powerful method that allows to study the low-energy properties of strongly interacting 1D quantum bosons systems.[11–14] The density operators $\rho_{n}\left(x\right),n=1,\ldots,N$ can be expressed in terms of N bosonic quantum fields $\varphi_{n}(x)$ through:[14]

$$\rho_{n}\left(x\right)\simeq\left[\rho_{0}+\frac{1}{\sqrt{\pi}}\partial_{x}\varphi_{n}\left(x\right)\right]\sum_{m=-\infty}^{\infty}\alpha_{m}e^{2im\left(\sqrt{\pi}\varphi_{n}(x)+\pi\rho_{0}x\right)},\tag{9}$$

where α_{m} are non-universal constants and ρ_{0} is the average density in each tube around which the fluctuations take place. We introduce the dual bosons ϑ_{n} associated to the fields φ_{n} such that $[\varphi_{n}(x_{1}),\partial_{x}\vartheta_{m}(x_{2})]=i\delta_{nm}\delta(x_{1}-x_{2})$. They allow us to describe the phase fluctuations of the boson creation operator $\Psi_{n}^{\dagger}$:

$$\begin{aligned}\Psi_{n}^{\dagger}\left(x\right)\;&\simeq\;\left[\rho_{0}+\frac{1}{\sqrt{\pi}}\partial_{x}\varphi_{n}\left(x\right)\right]^{1/2}\exp\left(i\sqrt{\pi}\vartheta_{n}\left(x\right)\right)\\&\times\sum_{m=-\infty}^{\infty}\beta_{m}e^{2im\left(\sqrt{\pi}\varphi_{n}(x)+\pi\rho_{0}x\right)},\end{aligned}\tag{10}$$

β_{m} being non-universal constants. In practice, one often only needs the leading parts of the expansions (9,10):

$$\begin{aligned}\rho_{n}\left(x\right)\;&\sim\;\rho_{0}+\frac{1}{\sqrt{\pi}}\partial_{x}\varphi_{n}\left(x\right)\\&\qquad+2\rho_{0}\cos\left(\sqrt{4\pi}\,\varphi_{n}\left(x\right)+2\pi\rho_{0}x\right)\\\Psi_{n}^{\dagger}\left(x\right)\;&\sim\;\sqrt{\rho_{0}}\,\exp\left(i\sqrt{\pi}\vartheta_{n}\left(x\right)\right).\end{aligned}\tag{11}$$

After investigation of the effects of these leading parts, the higher harmonics and less relevant terms can then be studied a posteriori.

In the absence of intertube coupling, the low-energy properties of the Hamiltonian (2) are described by the Tomonaga-Luttinger model:[34]

$$\mathcal{H}_{\mathrm{intra}}=\sum_{n=1}^{N}\int dx\,\frac{v}{2}\left[K\left(\partial_{x}\varphi_{n}\right)^{2}+\frac{1}{K}\left(\partial_{x}\vartheta_{n}\right)^{2}\right],\tag{12}$$

where the velocity v, and the Luttinger parameter K depend on the microscopic details of the original model. The Luttinger parameter has been determined numerically as function of the dipole coupling constant C_{dd} and the average density ρ_{0}.[30,34] In sharp contrast to bosonic gases with contact interactions where $K\geq1$, K can be much smaller than 1 for dipolar interactions.

The leading-part of the intertube interaction (3) can be expressed in terms of the boson fields φ_{n} and ϑ_{n} using Eq. (11):

$$\begin{aligned}\mathcal{H}_{\mathrm{inter}}\;&=\;\int dx\sum_{n=1}^{N-1}\left[-\frac{g_{\perp}}{a^{2}}\cos\left(\sqrt{\pi}\left(\vartheta_{n+1}-\vartheta_{n}\right)\right)\right.\\&-\;\left.\frac{g_{d}}{a^{2}}\cos\left(\sqrt{4\pi}\left(\varphi_{n+1}-\varphi_{n}\right)\right)\right]\\&+\;\lambda\int dx\sum_{n=1}^{N-1}\partial_{x}\varphi_{n+1}\partial_{x}\varphi_{n},\end{aligned}\tag{13}$$

$a\sim1/\rho_{0}$ being the short distance cut off (the average interparticle distance). For the attractive dipole-dipole interaction (7), the coupling constants read as follows :

$$\begin{aligned}g_{\perp}\;&=\;2\rho_{0}a^{2}J_{\perp}\\g_{d}\;&=\;\frac{C_{dd}\rho_{0}^{2}a^{2}}{\pi d^{3}}\\\lambda\;&=\;-\frac{C_{dd}}{2\pi^{2}d^{3}}.\end{aligned}\tag{14}$$

At this point, it is worth noting that the sign of the two cosine operators of Eq. (13) can be changed by the canonical transformation on the bosonic fields:

$$\begin{aligned}\varphi_{2n}\;&\rightarrow\;\varphi_{2n}+\frac{\sqrt{\pi}}{4},\;\;\varphi_{2n+1}\rightarrow\varphi_{2n+1}\\\vartheta_{2n}\;&\rightarrow\;\vartheta_{2n}+\sqrt{\pi},\;\;\vartheta_{2n+1}\rightarrow\vartheta_{2n+1}.\end{aligned}\tag{15}$$

so that the case of attractive and repulsive intertube interactions, such as (6) in particular, can be treated on the same footing by using the transformation (15).

Let us discuss the different terms that appear in the interacting Hamiltonian (13). They are of very different nature. The forward scattering term with the coupling constant λ will renormalize the velocity and Luttinger parameter of the bosonic modes. Now, the structure of the remaining terms is intriguing. They describe the competition between the bosonic fields φ_n and their dual fields ϑ_n. The low-energy effective Hamiltonian (13) is, in fact, similar to the competition between superconductivity and charge-density wave (CDW) in spin-gap electronic ladder systems,[35,36] the two first terms in Eq. (13) being respectively the analogues of the Josephson and CDW interactions. Their scaling dimensions with respect to the Luttinger-liquid fixed point (12) are respectively $\Delta_\perp = 1/(2K)$, $\Delta_d = 2K$. For $1/4 < K < 1$, which is a regime that can reached with dipole-dipole interactions, they are strongly relevant perturbations. The infrared (IR) properties of the system is then governed by the effective Hamiltonian:

$$\begin{aligned} \mathcal{H}_{\rm eff} &= \sum_{n=1}^{N} \int dx \, \frac{v}{2} \left[K \left(\partial_x \varphi_n\right)^2 + \frac{1}{K} \left(\partial_x \vartheta_n\right)^2 \right] \\ &- \int dx \sum_{n=1}^{N-1} \left[\frac{g_\perp}{a^2} \cos\left(\sqrt{\pi}\left(\vartheta_{n+1} - \vartheta_n\right)\right) \right. \\ &+ \left. \frac{g_d}{a^2} \cos\left(\sqrt{4\pi}\left(\varphi_{n+1} - \varphi_n\right)\right) \right], \end{aligned} \tag{16}$$

where the marginal forward scattering term has been discarded.

Our strategy thus consists in, first investigating the physical properties of model (16), and then, analysing the main effect of less relevant perturbations omitted in (16), such as the forward scattering and higher harmonics of the bosonized representations (9,10).

One can anticipate on symmetry grounds that the strongly relevant terms of model (16) will not introduce a spectral gap for all degrees of freedom. Indeed, it is straightforward to see that the model is invariant under two independent global U(1) transformations:

$$\begin{aligned} \varphi_n &\to \varphi_n + \alpha \\ \vartheta_n &\to \vartheta_n + \beta, \end{aligned} \tag{17}$$

α, β being real numbers. Introducing left and right components of the bosonic fields $\varphi_{nL,R} = (\varphi_n \pm \vartheta_n)/2$, the transformation (17) gives a $\mathrm{U}(1)_L \times \mathrm{U}(1)_R$ global continuous symmetry of model (16). We thus expect the model to be gapless with one bosonic field protected by the symmetry (17).

One way to reveal the emergence of this bosonic mode is to single it out by performing a change of basis on the bosons fields. In this respect, we thus introduce the bosonic field $\Phi_{0R,L}$, and $N-1$ other fields $\Phi_{lR,L}$ $(l = 1, \ldots, N-1)$ as follows:

$$\begin{aligned} \Phi_{0R(L)} &= \frac{1}{\sqrt{N}} \left(\varphi_1 + \ldots + \varphi_N\right)_{R(L)} \\ \Phi_{lR(L)} &= \frac{1}{\sqrt{l(l+1)}} \left(\varphi_1 + \ldots + \varphi_l - l\varphi_{l+1}\right)_{R(L)} \end{aligned} \tag{18}$$

Note that in the context of condensed matter physics, the boson $\Phi_{0R,L}$ would be called the charge boson since it is simply the sum of all bosons and describes fluctuations of the total charge. The inverse transformation can be easily found; we do not however need its explicit form but only some of its general properties:

$$\varphi_{nR(L)} = \frac{1}{\sqrt{N}} \Phi_{0R(L)} + \mathbf{v}^{(n)} \cdot \mathbf{\Phi}_{R(L)}, \tag{19}$$

where $\mathbf{\Phi}$ is the $N-1$ dimensional vector with components Φ_l $(l = 1, \ldots, N-1)$ and the N vectors $\mathbf{v}^{(n)}$ $(n = 1, \ldots, N)$ satisfy the following relations:

$$\begin{aligned} \mathbf{v}^{(n)} \cdot \mathbf{v}^{(m)} &= \delta_{nm} - \frac{1}{N} \\ \sum_{n=1}^{N} \mathbf{v}^{(n)} &= \mathbf{0} \\ \sum_{n=1}^{N} v_p^{(n)} v_q^{(n)} &= \delta_{pq}, \end{aligned} \tag{20}$$

with $p, q = 1, \ldots, N-1$. In the new basis, the effective Hamiltonian (16) simplifies as follows:

$$\begin{aligned} \mathcal{H}_{\rm eff} &= \int dx \, \frac{v}{2} \left[K \left(\partial_x \Phi_0\right)^2 + \frac{1}{K} \left(\partial_x \Theta_0\right)^2 \right] \\ &+ \int dx \, \frac{v}{2} \left[K \left(\partial_x \mathbf{\Phi}\right)^2 + \frac{1}{K} \left(\partial_x \mathbf{\Theta}\right)^2 \right] \\ &- \int dx \sum_{n=1}^{N-1} \left[\frac{g_\perp}{a^2} \cos\left(\sqrt{\pi}\left(\mathbf{v}^{(n+1)} - \mathbf{v}^{(n)}\right) \cdot \mathbf{\Theta}\right) \right. \\ &+ \left. \frac{g_d}{a^2} \cos\left(\sqrt{4\pi}\left(\mathbf{v}^{(n+1)} - \mathbf{v}^{(n)}\right) \cdot \mathbf{\Phi}\right) \right], \end{aligned} \tag{21}$$

where Θ_0 and $\mathbf{\Theta}$ are respectively the dual fields of Φ_0 and $\mathbf{\Phi}$. It is interesting to observe that the low-energy effective theory (21) has been found in total different contexts. On the one hand, the deconfining phase transition of the 2+1-dimensional SU(N) Georgi-Glashow model is controlled by model (21).[37] On the other hand, as shown recently, it describes the Read-Rezayi sequence of non-Abelian fractional quantum Hall states.[38] We explicitly observe, from Eq. (21), that the Φ_0 field decouples from the interaction terms and remains gapless. We now need to analyse the fate of the remaining degrees of freedom. The low-energy properties of the model depend on the value of K which controls the competition between the $\mathbf{\Phi}$ and $\mathbf{\Theta}$ fields of Eq. (21).

When $1/2 < K < 1$, the most relevant contribution is the dual field $\mathbf{\Theta}$ term with scaling dimension $\Delta_\perp = 1/(2K)$. This field is pinned onto the minima of its sine-Gordon model in Eq. (21) with coupling constant $g_\perp > 0$: $\langle \mathbf{\Theta} \rangle = \mathbf{0}$. In contrast, the bosonic $\mathbf{\Phi}$ field is a strongly fluctuating field being dual to $\mathbf{\Theta}$. The resulting phase is a superfluid phase which is described by the following leading asymptotics of equal-time correlation functions:

$$\begin{aligned} \langle \Psi_n^\dagger(x)\, \Psi_m(0) \rangle &\sim x^{-1/(2NK)} \\ \langle \rho_n(x)\, \rho_m(0) \rangle &\sim \rho_0^2 - \frac{K}{2N\pi^2 x^2}. \end{aligned} \tag{22}$$

In particular, the $2\pi\rho_0$ oscillations of the density ρ_n are short-ranged.

When $K < 1/2$, the most relevant contribution of Eq. (21) is now the term with the bosonic field $\mathbf{\Phi}$, with scaling dimension $\Delta_d = 2K$. The bosonic field $\mathbf{\Phi}$ is pinned onto the minima of its sine-Gordon model with coupling constant $g_d > 0$: $\langle \mathbf{\Phi} \rangle = \mathbf{0}$. In this phase, the bosonic $\mathbf{\Theta}$ field is a strongly fluctuating field. The resulting phase is a CDW phase, or a density-wave phase, where the intratube density are all in phase:

$$\begin{aligned} \langle \Psi_n^\dagger (x) \, \Psi_m (0) \rangle \; &\sim \; e^{-x/\xi} \\ \langle \rho_n (x) \, \rho_m (0) \rangle \; &\sim \; \rho_0^2 + A \frac{\cos (2\pi\rho_0 x)}{x^{2K/N}}, \end{aligned} \qquad (23)$$

ξ being the correlation length which stems from the spectral gap opened by the relevant perturbation of Eq. (21) with coupling constant g_d, and A is a non-universal constant. While the bosonic creation operator has short-ranged correlations, this phase allows the formation between the tubes of a molecular superfluid instability made of N bosons. Indeed, using the bosonization approach (11), we find that the operator $M^\dagger = \Psi_1^\dagger \Psi_2^\dagger \dots \Psi_N^\dagger$ is described by $M^\dagger \sim e^{i\sqrt{\pi}\sum_{n=1}^{N} \vartheta_n} = e^{i\sqrt{\pi N}\Theta_0}$. We deduce thus the leading asymptotics of molecular superfluid correlation function:

$$\langle M^\dagger (x) \, M (0) \rangle \sim x^{-N/(2K)}. \qquad (24)$$

This instability dominates the density wave (23) only if $K > N/2$. The situation is in close parallel to the formation of molecular fermionic superfluid instability in 1D multicomponent cold fermionic atoms.[39–44]

For decoupled tubes, it is well known that the superfluid correlations are dominant when $K > 1/2$ while the CDW is the leading instability for $K < 1/2$.[12] There is a smooth crossover at $K = 1/2$ between these two regions. But as we can see from Eqs. (22, 23), here the situation is in stark contrast to the decoupled tubes case, since $K = 1/2$ marks the onset of a zero-temperature quantum phase transition. At $K = 1/2$, the competition between the bosonic fields and their dual is maximal since the two strongly relevant perturbations have the same scaling dimension $\Delta_\perp = \Delta_d = 1$:

$$\begin{aligned} \mathcal{H}_{\text{eff}} \; &= \; \sum_{n=1}^{N} \int dx \, \frac{v}{2} \left[(\partial_x \varphi_n)^2 + (\partial_x \vartheta_n)^2 \right] \\ &- \; \int dx \, \sum_{n=1}^{N-1} \left[\frac{g_\perp}{a^2} \cos \left(\sqrt{2\pi} \, (\vartheta_{n+1} - \vartheta_n) \right) \right. \\ &+ \; \left. \frac{g_d}{a^2} \cos \left(\sqrt{2\pi} \, (\varphi_{n+1} - \varphi_n) \right) \right]. \end{aligned} \qquad (25)$$

B. Non-Abelian symmetry

The effective Hamiltonian (25) at $K = 1/2$ displays a hidden SU(2) symmetry when $g_\perp = g_d$.[35,36] In this respect, it is worth introducing the following family of SU(2) matrices:

$$g_n = \frac{1}{\sqrt{2}} \begin{pmatrix} e^{-i\sqrt{2\pi}\varphi_n} & i e^{-i\sqrt{2\pi}\vartheta_n} \\ i e^{i\sqrt{2\pi}\vartheta_n} & e^{i\sqrt{2\pi}\varphi_n} \end{pmatrix}, \qquad (26)$$

with $n = 1, \dots, N$. The interaction part, V_{eff}, of model (25) can be expressed in terms of these matrices:

$$\begin{aligned} V_{\text{eff}} \; &= \; \int dx \, \frac{1}{2a^2} \left[- (g_\perp + g_d) \, \text{Tr} \left(g_{n+1}^\dagger g_n \right) \right. \\ &+ \; \left. (g_\perp - g_d) \, \text{Tr} \left(g_{n+1}^\dagger \sigma_z g_n \sigma_z \right) \right], \end{aligned} \qquad (27)$$

σ_z being the third Pauli matrix. We conclude that the interaction term (27) displays a non-Abelian symmetry SU(2)$_L$ × SU(2)$_R$ for $g_\perp = g_d$ since it is then invariant under the symmetry: $g_n \to U g_n V$, U and V being two *independent* SU(2) matrices. When $g_\perp \neq g_d$, due to the last term of Eq. (27), this non-Abelian symmetry is broken down to U(1)$_L$ × U(1)$_R$ in full agreement with Eq. (17).

It is then natural to expect that the quantum phase transition between the superfluid and CDW phase occurs precisely at $g_\perp = g_d$ where the effective Hamiltonian (25) enjoys an enlarged SU(2)$_L$ × SU(2)$_R$ global symmetry as well as a self-dual symmetry $\varphi_n \leftrightarrow \vartheta_n$:

$$\begin{aligned} \mathcal{H}^* \; &= \; \sum_{n=1}^{N} \int dx \, \frac{v}{2} \left[(\partial_x \varphi_n)^2 + (\partial_x \vartheta_n)^2 \right] \\ &- \; \frac{g_d}{a^2} \int dx \, \sum_{n=1}^{N-1} \left[\cos \left(\sqrt{2\pi} \, (\vartheta_{n+1} - \vartheta_n) \right) \right. \\ &+ \; \left. \cos \left(\sqrt{2\pi} \, (\varphi_{n+1} - \varphi_n) \right) \right]. \end{aligned} \qquad (28)$$

The existence of this global SU(2)$_L$ × SU(2)$_R$ continuous symmetry leads us to expect that model (28) displays quantum critical properties which are governed by some CFT. Due to the SU(2)$_L$ × SU(2)$_R$ invariance, the natural candidate is the SU(2)$_k$ CFT with central charge $c = 3k/(k+2)$, where k is some integer to be determined. In the next subsection, we are going to show non-perturbatively that the model (28) is indeed conformally invariant for all sign of g_d, and belongs to the SU(2)$_N$ universality class.

C. Conformal embedding approach

Let us now consider the CFTs underlying the physics of our system at the Luttinger-liquid fixed point, i.e. when the intertube interactions are turned off, $g_\perp = g_d = 0$.

At $K = 1/2$, each boson field φ_n ($n = 1, \dots, N$) is a compactified boson with radius $R = 1/\sqrt{2\pi}$: $\varphi_n \sim \varphi_n + 2\pi R$, $\vartheta_n \sim \vartheta_n + 2\pi R$. This equivalence can be viewed as gauge redundancy in the description since the density and creation operators (9,10) for $K = 1/2$ are invariant under that transformation. At this special radius, each boson field φ_n describes an SU(2)$_1$ CFT with central charge $c = 1$. These CFTs are each generated by left and right $\mathrm{SU(2)}_1$ currents $\mathbf{j}_{nR,L}$ which read as follows in terms of the left-right moving bosons (see Appendix Sec. 1 for more details):

$$\begin{aligned} j^{\dagger}_{nR,L} &= \frac{1}{2\pi a}\exp(\mp i\sqrt{8\pi}\,\varphi_{nR,L}) \\ j^{z}_{nR,L} &= \frac{1}{\sqrt{2\pi}}\partial_x\varphi_{nR,L}. \end{aligned} \tag{29}$$

The SU(2) matrix (26) is the spin-1/2 $\mathrm{SU(2)}_1$ primary operator with scaling dimension $1/2$. The conformal symmetry of the non-interacting part of model (28) is then $\mathrm{SU(2)}_1 \times \mathrm{SU(2)}_1 \times \ldots \times \mathrm{SU(2)}_1$ with central charge N (i.e., N gapless bosonic modes). The N $\mathrm{SU(2)}_1$ currents (29) can then be combined to form an $\mathrm{SU(2)}_N$ current:

$$\mathbf{I}_{R,L} = \sum_{n=1}^{N}\mathbf{j}_{nR,L}. \tag{30}$$

The next step of the approach is to go from these N $\mathrm{SU(2)}_1$ CFTs to the $\mathrm{SU(2)}_N$ CFT with central charge $3N/(N+2)$. In this respect, one can use the following conformal embedding to investigate the critical properties of model (28):

$$\mathrm{SU(2)}_1 \times \mathrm{SU(2)}_1 \times \cdots \times \mathrm{SU(2)}_1 \rightarrow \mathrm{SU(2)}_N \times \mathcal{G}_N, \tag{31}$$

where $\mathcal{G}_N$ is a discrete CFT with central charge $c_{\mathcal{G}_N} = N - 3N/(N+2) = N(N-1)/(N+2)$. It is important to note that the latter central charge coincides with the sum of the central charges of the $N-1$ first minimal models:[37]

$$c_{\mathcal{G}_N} = \frac{N\left(N-1\right)}{\left(N+2\right)} = \sum_{m=2}^{N+1}\left(1-\frac{6}{m\left(m+1\right)}\right). \tag{32}$$

The $\mathcal{G}_N$ CFT is thus related to the product $\mathcal{M}_3 \times \mathcal{M}_4 \times \ldots \times \mathcal{M}_{N+1}$ where $\mathcal{M}_p$ denotes the minimal model series with central charge $c_p = 1-6/p(p+1)$; for $p = 3, 4, 5$ they respectively correspond to the Ising, TIM (Tricritical Ising Model), and $\mathbb{Z}_3$ Potts CFTs.[15] The precise identification requires a projection P: $\mathcal{G}_N \sim P(\mathcal{M}_3 \times \mathcal{M}_4 \ldots \times \mathcal{M}_{N+1})$, which has been described in Ref.45.

The central point of our analysis is to show that the self-dual perturbation of model (28):

$$\mathcal{V}_{\text{sd}} = \sum_{n=1}^{N-1}\cos(\sqrt{2\pi}(\varphi_{n+1}-\varphi_n)) + \cos(\sqrt{2\pi}(\vartheta_{n+1}-\vartheta_n)), \tag{33}$$

does not depend on the $\mathrm{SU(2)}_N$ CFT. More precisely, we show, in Sec. 2 of the Appendix, that the operator $\mathcal{V}_{\text{sd}}$ is indeed a singlet under the $\mathrm{SU(2)}_N$ CFT and a primary operator of the $\mathcal{G}_N$ CFT with a scaling dimension equal to one. Hence, since it is a strongly relevant perturbation, $\mathcal{V}_{\text{sd}}$ introduces a spectral gap for the discrete $\mathcal{G}_N$ degrees of freedom, but leaves the $\mathrm{SU(2)}_N$ ones intact. We thus conclude that model (28) displays critical properties in the $\mathrm{SU(2)}_N$ universality class for all signs of g_d.

However, we are not guaranteed that the critical properties of the initial model (1) are controlled by this $\mathrm{SU(2)}_N$ fixed point. One has to investigate the stability of the latter fixed point with respect to the marginal forward scattering operator of Eq. (13) and the contributions of the decoupled tubes limit such as the higher harmonics of the bosonized description (9,10) that we have neglected. The marginal forward-scattering process breaks the non-abelian $\mathrm{SU(2)}_L \times \mathrm{SU(2)}_R$ symmetry for $g_\perp = g_d$ down to $\mathrm{U(1)}_L \times \mathrm{U(1)}_R$. In this respect, the symmetry of the IR fixed point is then $\mathrm{U(1)} \times \mathbb{Z}_N$ since $\mathrm{SU(2)}_N/\mathrm{U(1)} \sim \mathbb{Z}_N$.[23,24] The latter CFT with central charge $c_N = 2(N-1)/(N+2)$ is called the $\mathbb{Z}_N$ parafermionic CFT and describes the multicritical properties of 2D $\mathbb{Z}_N$ generalization of Ising models.[23] The self-duality symmetry, $\varphi_n \leftrightarrow \vartheta_n$, of model (28) corresponds to the Kramers-Wannier (KW) self-duality symmetry of $\mathbb{Z}_N$ models. In fact, the $\mathbb{Z}_N$ symmetry can be defined directly in terms of the bosons at $K = 1/2$:

$$\begin{aligned} \vartheta_n &\rightarrow \vartheta_n + \frac{\sqrt{2\pi}}{N}m \\ \varphi_n &\rightarrow \varphi_n, \end{aligned} \tag{34}$$

with $m = 0, 1, \ldots, N-1$. Using the representation (10), this $\mathbb{Z}_N$ symmetry has a simple interpretation in terms of the original bosonic creation operators:

$$\Psi^{\dagger}_n\left(x\right) \rightarrow \Psi^{\dagger}_n\left(x\right)e^{i\frac{2\pi}{N}m}. \tag{35}$$

In general, the $\mathrm{SU(2)}_N$ and $\mathbb{Z}_N$ fixed points are fragile since they can be destabilized by several relevant primary operators. Here, the presence of the $\mathbb{Z}_N$ symmetry (34) does protect the system from several relevant perturbations. However, primary operators such as the thermal operators ϵ_k, with scaling dimensions $\Delta_k = 2k(k+1)/(N+2)$, with $k = 1, \ldots [N/2]$ ($[N/2]$ is the integer part of $N/2$), are invariant under the $\mathbb{Z}_N$ symmetry and might destabilize the IR fixed point. Fortunately, some of these operators, such as ϵ_1, can be killed by a special fine-tuning of the coupling constants by imposing the self-duality symmetry. Indeed, under the KW symmetry, one has $\epsilon_k \rightarrow -\epsilon_k$, and ϵ_1 disappears along the self-dual manifold the model. As a result, for small values of N, the $\mathrm{SU(2)}_N$ or $\mathrm{U(1)} \times \mathbb{Z}_N$ fixed point is likely to be stable thanks to the control of the dipole strength and the intertube hopping. In contrast, for $N \geq 5$, a strongly relevant self-dual perturbation ϵ_2 with scaling dimension $12/(N+2)$ will be generated in the $\mathbb{Z}_N$ sector. The resulting field theory which captures the quantum phase transition in this case becomes:

$$\mathcal{S}_{\text{eff}} = \mathcal{S}_{\mathbb{Z}_N} + \lambda\int d^2x\,\epsilon_2\left(x\right), \tag{36}$$

where $\mathcal{S}_{\mathbb{Z}_N}$ stands for the action of the $\mathbb{Z}_N$ CFT. Model (36) turns out to be an integrable deformation of the $\mathbb{Z}_N$ CFT.[46,47] The nature of the phase transition depends on the sign of the coupling constant λ.[46,47] For $\lambda < 0$, the field theories (36) are massive and the phase transition is of first-order type. For $\lambda > 0$ it is known that model (36) has a massless renormalization-group flow onto a Kosterlitz-Thouless (KT) U(1) gapless phase with central charge $c = 1$. In the latter case, there is an intermediate gapless phase between the superfluid and CDW phases for $N \geq 5$. Adding the contribution of the gapless mode Φ_0, this phase displays extended quantum criticality with central charge $c = 2$. Unfortunately, our approach does not enable us to fix the sign of the perturbation of model (36) and we cannot discriminate between the two possibilities for the nature of the transition for $N \geq 5$. In the following, we will investigate the nature of the quantum phase transition for small values of N, i.e., $N = 2, 3$, which respectively correspond to double-tube and triple-tube systems.

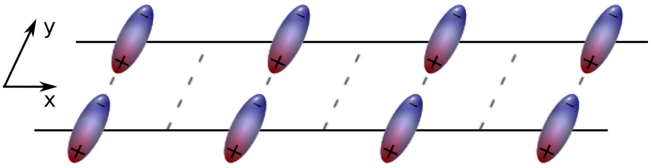

FIG. 2: (color online) The CDW order characterized by Eq. (44); the two CDW orders in each tube are in phase.

III. DOUBLE-TUBE SYSTEM

In this section, we determine the zero-temperature physical properties of the double-tube system which corresponds to model (1) with $N = 2$ (see Fig. (2)).

The harmonic-fluid representation (12, 13) simplifies as follows in the $N = 2$ case:

$$\begin{aligned} \mathcal{H}_{N=2} &= \int dx\, \frac{v}{2}\left[K\left(\partial_x\varphi_1\right)^2 + \frac{1}{K}\left(\partial_x\vartheta_1\right)^2 + 1 \to 2\right] \\ &- \int dx\, \left[\frac{g_\perp}{a^2}\cos\left(\sqrt{\pi}\left(\vartheta_2 - \vartheta_1\right)\right)\right. \\ &+ \left.\frac{g_d}{a^2}\cos\left(\sqrt{4\pi}\left(\varphi_2 - \varphi_1\right)\right)\right] \\ &+ \lambda \int dx\, \partial_x\varphi_2\partial_x\varphi_1. \end{aligned} \tag{37}$$

The next step is to use the change of basis (18):

$$\begin{aligned} \Phi_{0R(L)} &= \frac{1}{\sqrt{2}}\left(\varphi_1 + \varphi_2\right)_{R(L)} \\ \Phi_{1R(L)} &= \frac{1}{\sqrt{2}}\left(\varphi_1 - \varphi_2\right)_{R(L)}, \end{aligned} \tag{38}$$

so that we obtain

$$\begin{aligned} \mathcal{H}_{N=2} &= \int dx\, \frac{v_0}{2}\left[K_0\left(\partial_x\Phi_0\right)^2 + \frac{1}{K_0}\left(\partial_x\Theta_0\right)^2\right] \\ &+ \int dx\, \frac{v_1}{2}\left[K_1\left(\partial_x\Phi_1\right)^2 + \frac{1}{K_1}\left(\partial_x\Theta_1\right)^2\right] \\ &- \int dx\, \left[\frac{g_\perp}{a^2}\cos\left(\sqrt{2\pi}\Theta_1\right) + \frac{g_d}{a^2}\cos\left(\sqrt{8\pi}\Phi_1\right)\right]. \end{aligned} \tag{39}$$

There is a velocity anisotropy and two different Luttinger parameters which stem from the marginal term of Eq. (37) with coupling constant λ:

$$\begin{aligned} K_0 &= \frac{K}{\sqrt{1 + \lambda v/K}} \\ K_1 &= \frac{K}{\sqrt{1 - \lambda v/K}}. \end{aligned} \tag{40}$$

The effective Hamiltonian (39) has been first studied in Ref.48 in the context of a bosonic two-leg ladder for incommensurate filling. It separates into two commuting pieces: $\mathcal{H}_{N=2} = \mathcal{H}_0 + \mathcal{H}_1$ ($[\mathcal{H}_0, \mathcal{H}_1] = 0$). The first contribution $\mathcal{H}_0$ of Eq. (39) has the form of a Tomonaga-Luttinger Hamiltonian; this signals that the bosonic field Φ_0 is a gapless degree of freedom. All the non-trivial physics is encoded in $\mathcal{H}_1$ which describes the competition between the intertube hopping and dipole-dipole interactions. As already discussed in Sec. II in the general N case, there are two different phases which stem from this competition. When $1/2 < K_1 < 1$, $\mathcal{H}_1$ has a spectral gap Δ_1 due to the cosine term with the bosonic field Θ_1. As a result, Θ_1 is pinned onto one of the minima of its sine-Gordon model, which we can choose to be $\langle\Theta_1\rangle = 0$ ($g_\perp > 0$). Thus, at low-energy $E \ll \Delta_1$, the creation operator of the bosons simplifies as follows: $\Psi_n^\dagger \sim \sqrt{\rho_0}\, e^{i\sqrt{\pi/2}\,\Theta_0}$, while the $2\pi\rho_0$ density operator is short-ranged since it depends on the strongly fluctuating field Φ_1. The resulting superfluid phase is then characterized by:

$$\begin{aligned} \langle\Psi_n^\dagger(x)\,\Psi_m(0)\rangle &\sim x^{-1/(4K_0)} \\ \langle\rho_n(x)\,\rho_m(0)\rangle &\sim \rho_0^2 - \frac{K_0}{4\pi^2x^2}, \end{aligned} \tag{41}$$

with $n, m = 1, 2$. In fact, in this phase, one may also consider the symmetric combination of the density with $4\pi\rho_0$ oscillations in each tube:

$$\begin{aligned} \rho^{4\pi\rho_0} &\sim \rho_0 \sum_{n=1}^{2}\cos\left(4\pi\rho_0 x + 4\sqrt{\pi}\varphi_n\right) \\ &\sim 2\rho_0\cos\left(4\pi\rho_0 x + \sqrt{8\pi}\Phi_0\right)\cos\left(\sqrt{8\pi}\Phi_1\right). \end{aligned} \tag{42}$$

This operator is naively short-ranged in the phase with $\langle\Theta_1\rangle = 0$ since it depends on the field Φ_1. However, first-order perturbation theory with the Hamiltonian $\mathcal{H}_1$ cancels the contribution of $\cos\left(\sqrt{8\pi}\Phi_1\right)$ in $\rho^{4\pi\rho_0}$. The low-energy description of that operator in the superfluid phase thus simplifies as follows:

$$\rho^{4\pi\rho_0} \sim 2\rho_0\cos\left(4\pi\rho_0 x + \sqrt{8\pi}\Phi_0\right). \tag{43}$$

We deduce that the two-point correlation function of that operator has a power-law decay with exponent $4K_0$. Since $1/2 < K_0 < 1$, the decay is much slower than the decays of the instabilities of Eq. (41).

The second phase is obtained when $K_1 < 1/2$. The most relevant contribution of Eq. (39) is now the cosine term with the bosonic field Φ_1 which is pinned: $\langle\Phi_1\rangle = 0$ ($g_d > 0$). In this phase, the dual field Θ_1 is a strongly fluctuating field. The resulting phase is a CDW phase where the two $2\pi\rho_0$ CDW on each tube are in phase (see Fig. 2):

$$\begin{aligned} \langle \Psi_n^{\dagger}\left(x\right) \Psi_m\left(0\right)\rangle &\sim e^{-x/\xi} \\ \langle \rho_n\left(x\right) \rho_m\left(0\right)\rangle &\sim \rho_0^2 + A\frac{\cos\left(2\pi\rho_0 x\right)}{x^{K_0}}, \end{aligned} \tag{44}$$

A being a non-universal constant and $\xi \sim v_1/\Delta_1$ is the correlation length which stems from the spectral gap of the Hamiltonian $\mathcal{H}_1$. In this phase, the dimer instability $M^{\dagger} = \Psi_1^{\dagger}\Psi_2^{\dagger} \sim \rho_0\, e^{i\sqrt{2\pi}\,\Theta_0}$ has a power-law correlation function with a larger decay $1/K_0$ ($K_0 < 1$).

The quantum phase transition between these two different phases occurs at $K_1 = 1/2$. From Eq. (40), we observe that since $\lambda < 0$, we have $K_1 < K$, i.e., attractive intertube interactions such as in Eq. (7) are favorable in order to reach the transition. The effective Hamiltonian which governs this transition writes:

$$\begin{aligned} \mathcal{H}_{\text{eff}} &= \int dx\, \frac{v_1}{2}\left[\left(\partial_x\Phi_1\right)^2 + \left(\partial_x\Theta_1\right)^2\right] \\ &- \int dx\, \left[\frac{g_{\perp}}{a^2}\cos\left(\sqrt{4\pi}\Theta_1\right) + \frac{g_d}{a^2}\cos\left(\sqrt{4\pi}\Phi_1\right)\right]. \end{aligned} \tag{45}$$

This model is well known (see e.g. Ref.49) and can be exactly diagonalized by introducing two Majorana fermions $\xi^{1,2}$. This procedure is nothing but the standard bosonization of two Ising models.[16,50,51] The refermionization rules are given by

$$\begin{aligned} \xi_R^1 + i\xi_R^2 &= \frac{1}{\sqrt{\pi a}}\exp\left(i\sqrt{4\pi}\Phi_{1R}\right), \\ \xi_L^1 + i\xi_L^2 &= \frac{1}{\sqrt{\pi a}}\exp\left(-i\sqrt{4\pi}\Phi_{1L}\right), \end{aligned} \tag{46}$$

where the anticommutation between the right and left-moving Majorana fermions is taken into account by the prescription: $[\Phi_{1R}, \Phi_{1L}] = i/4$. The effective Hamiltonian can then be refermionized:

$$\begin{aligned} \mathcal{H}_{\text{eff}} &= -\frac{iv_1}{2}\int dx\, \sum_{a=1}^{2}\left(\xi_R^a\partial_x\xi_R^a - \xi_L^a\partial_x\xi_L^a\right) \\ &- \int dx\, \left[im_1\xi_R^1\xi_L^1 + im_2\xi_R^2\xi_L^2\right], \end{aligned} \tag{47}$$

where the two masses are given by:

$$\begin{aligned} m_1 &= \left(g_d - g_{\perp}\right)/a \\ m_2 &= \left(g_d + g_{\perp}\right)/a. \end{aligned} \tag{48}$$

The effective model (45) at $K_1 = 1/2$ is thus mapped onto two decoupled 1D Ising models in a transverse field. The Majorana fermion $\xi_{R,L}^2$ always has a positive mass m_2 which means that, in our convention, the corresponding Ising model belongs to its disordered phase where the disorder operator condenses: $\langle\mu_2\rangle \neq 0$. In contrast, the Majorana fermion $\xi_{R,L}^1$ has a smaller mass m_1 which can change its sign; by tuning the hopping $g_{\perp}$, we are thus able to reach the Ising $\mathbb{Z}_2$ quantum critical point where $m_1 = 0$.

The different order parameters defined in Eqs. (41, 44) can be expressed in terms of the Ising order ($\sigma_{1,2}$) and disorder ($\mu_{1,2}$) parameters of the two underlying Ising models. In this respect, we need the Ising description of all the vertex operators with a scaling dimension equal to $1/4$:[50–54]

$$\begin{aligned} \sqrt{2}\cos(\sqrt{\pi}\Phi_1) &\sim \mu_1\mu_2,\ \sqrt{2}\cos(\sqrt{\pi}\Theta_1) \sim \sigma_1\mu_2 \\ \sqrt{2}\sin(\sqrt{\pi}\Phi_1) &\sim \sigma_1\sigma_2,\ \sqrt{2}\sin(\sqrt{\pi}\Theta_1) \sim \mu_1\sigma_2, \end{aligned} \tag{49}$$

where the Ising order parameters are normalized at the $\mathbb{Z}_2$ quantum critical point according to:

$$\langle\sigma_a\left(\tau, x\right)\sigma_b\left(0, 0\right)\rangle = \frac{\delta_{ab}}{\left(v_1^2\tau^2 + x^2\right)^{1/8}}, \tag{50}$$

with $a, b = 1, 2$, and similarly for the two-point correlations of the Ising disorder operators. At low-energy, i.e., $E \ll m_2$, we can average the operators of the second Ising model ($\langle\mu_2\rangle \neq 0$ and $\langle\sigma_2\rangle = 0$). The bosonic creation and density operators then simplify as follows, using Eq. (49):

$$\begin{aligned} \Psi_n^{\dagger} &\sim e^{i\sqrt{\pi/2K_0}\,\Theta_0}\sigma_1 \\ \rho_n &\sim \rho_0 + \sqrt{\frac{K_0}{2\pi}}\partial_x\Phi_0 \\ &\qquad + \sqrt{A}\cos\left[2\pi\rho_0 x + \sqrt{2\pi K_0}\Phi_0\right]\mu_1, \end{aligned} \tag{51}$$

with $K_0 \simeq 1/2$. In particular, we observe that the bosonic creation operator expresses in terms of the Ising order operator σ_1, in full agreement with the identification of the discrete $\mathbb{Z}_N$ symmetry (35) made in Sec. II.

It is then straightforward to deduce the zero-temperature phase diagram of model (45). When $g_{\perp} < g_d$, i.e. $m_1 > 0$, the Ising model belongs to its disorder phase with $\langle\sigma_1\rangle = 0$ and $\langle\mu_1\rangle \neq 0$. We recover the CDW phase with the leading asymptotics (44). When $g_{\perp} > g_d$, the Ising model belongs to its ordered phase with $\langle\sigma_1\rangle \neq 0$ and the double-tube system sits in its superfluid phase (41). The quantum phase transition between these two phases occurs for $g_{\perp} = g_d$ and is driven by the Ising degrees of freedom. The resulting critical properties are determined by the low-energy description (51) and correlations (50):

$$\begin{aligned} \langle\Psi_n^{\dagger}\left(x\right)\Psi_m\left(0\right)\rangle &\sim x^{-1/(4K_0)-1/4} \\ \langle\rho_n\left(x\right)\rho_m\left(0\right)\rangle &\sim \rho_0^2 - \frac{K_0}{4\pi^2x^2} + A\frac{\cos\left(2\pi\rho_0 x\right)}{x^{K_0+1/4}}, \end{aligned} \tag{52}$$

with $K_0 \simeq 1/2$. The quantum phase transition is thus described by a U(1) × $\mathbb{Z}_2$ CFT with a central charge $c = 1 + 1/2 = 3/2$. The SU(2)$_2$ critical properties of the perturbation (33) for $N = 2$ are weakly broken down to U(1) × $\mathbb{Z}_2$ since the bosonic fields Φ_0 and Φ_1 have different Luttinger parameters (40) and velocities.

IV. TRIPLE-TUBE SYSTEMS

In this section, we determine the zero-temperature physical properties of the triple-tube system which corresponds to model (1) with $N = 3$ (see Fig. 3). We consider here two different geometries: one with open-boundary conditions (Fig. 3(a)) and the other with periodic boundary conditions, where the tubes form an equilateral triangle (see Fig. 3(b)). In the latter case, we assume a non-frustrated situation where all intertube density-density interactions are attractive.

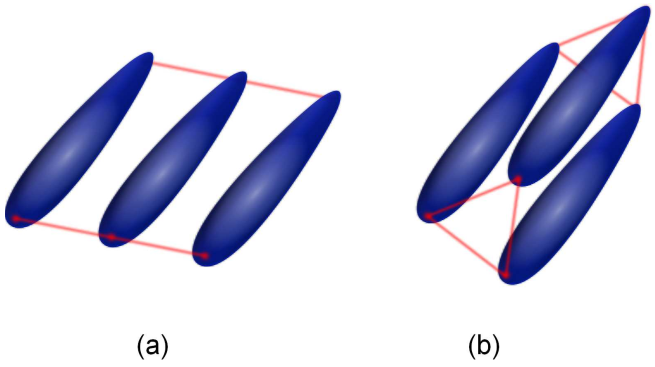

FIG. 3: A triple-tube system for (a) open boundary conditions; (b) periodic boundary conditions. As in Fig. 1, the tubes are separated by a distance d.

A. $\mathbb{Z}_3$ emerging quantum criticality

The harmonic-fluid representation for the triple-tube system of Fig. 3(a) is given by model (12, 13) with $N = 3$. Here, we follow the general strategy of Sec. II and first consider the most relevant contribution, i.e. Eq. (16) with $N = 3$. We single out the gapless U(1) Φ_0 bosonic field by switching to the basis (18) with $N = 3$. The inverse transformation (19) explicitly reads as follows:

$$\begin{aligned} \varphi_1 &= \frac{1}{\sqrt{3}}\Phi_0 + \frac{1}{\sqrt{2}}\Phi_1 + \frac{1}{\sqrt{6}}\Phi_2 \\ \varphi_2 &= \frac{1}{\sqrt{3}}\Phi_0 - \frac{2}{\sqrt{6}}\Phi_2 \\ \varphi_3 &= \frac{1}{\sqrt{3}}\Phi_0 - \frac{1}{\sqrt{2}}\Phi_1 + \frac{1}{\sqrt{6}}\Phi_2, \end{aligned} \tag{53}$$

with similar definitions for the dual fields $\vartheta_{1,2,3}$. The effective Hamiltonian (16) for $N = 3$ separates into two commuting pieces: $\mathcal{H}_{\text{eff}} = \mathcal{H}_0 + \mathcal{H}_s$, where $\mathcal{H}_0$ takes the form of the Tomonaga-Luttinger model:

$$\mathcal{H}_0 = \int dx \, \frac{v}{2} \left[K \left(\partial_x \Phi_0\right)^2 + \frac{1}{K} \left(\partial_x \Theta_0\right)^2 \right]. \tag{54}$$

The remaining degrees of freedom in $\mathcal{H}_s$ are strongly coupled and control the quantum phase transition between the superfluid phase (22) and the CDW phase (23) at $K = 1/2$. When $K = 1/2$ and in the new basis, the effective Hamiltonian for these degrees of freedom is given by:

$$\begin{aligned} \mathcal{H}_s = &\int dx \, \frac{v}{2} \left[(\partial_x \Phi_1)^2 + (\partial_x \Theta_1)^2 + 1 \rightarrow 2 \right] \\ - &\int dx \, \left[\frac{2g_\perp}{a^2} \cos\left(\sqrt{\pi}\,\Theta_1\right) \cos\left(\sqrt{3\pi}\,\Theta_2\right) \right. \\ + &\left. \frac{2g_d}{a^2} \cos\left(\sqrt{\pi}\Phi_1\right) \cos\left(\sqrt{3\pi}\Phi_2\right) \right]. \end{aligned} \tag{55}$$

The bosonic field Φ_1 is at the free-fermion point, i.e. the terms of the form $\cos\left(\beta \Phi_1\right)$ or $\cos\left(\beta\ \Theta_1\right)$ that appear in the Hamiltonian all have $\beta = \sqrt{\pi}$. For this reason, we can introduce two effective Ising models with order parameters $\sigma_{1,2}$ and disorder fields $\mu_{1,2}$, so as to refermionize the vertex operators of Eq. (55) with a scaling dimension $1/4$, just as we did for the double-tube system (see Eq. (49)):

$$\begin{aligned} \mathcal{H}_s = &-\frac{iv}{2} \int dx \, \sum_{a=1}^{2} \left(\xi_R^a \partial_x \xi_R^a - \xi_L^a \partial_x \xi_L^a \right) \\ + &\int dx \, \frac{v}{2} \left[(\partial_x \Phi_2)^2 + (\partial_x \Theta_2)^2 \right] \\ - &\frac{\sqrt{2}}{a} \int dx \, \left[g_\perp \sigma_1 \mu_2 : \cos\left(\sqrt{3\pi}\ \Theta_2\right) : \right. \\ + &\left. g_d \mu_1 \mu_2 : \cos\left(\sqrt{3\pi} \Phi_2\right) : \right]. \end{aligned} \tag{56}$$

The next step of the approach is to switch to a different basis to determine the main effect of the relevant perturbation of model (56). In this respect, we exploit the fact that the CFT defined by the product of one Ising CFT (the one with disorder operator μ_1) and the CFT associated to the boson Φ_2, can be described in terms of the product $\mathcal{M}_4 \times \mathcal{M}_5$ CFT, i.e., TIM $\times$ $\mathbb{Z}_3$ Potts CFTs. Indeed, the TIM and the $\mathbb{Z}_3$ Potts CFTs have central charges $c = 7/10$ and $c = 4/5$ respectively, so that the sum gives $c = 3/2$, the total central charge of an Ising CFT $c = 1/2$ and a CFT associated with one boson $c = 1$. The TIM CFT describes the physical properties of the two-dimensional dilute Ising model at its tricritical point.[15,55] The precise identification of the conformal embedding has been derived by the authors of Ref.45 and requires a projection which restricts the primary operators of $\mathcal{M}_4 \times \mathcal{M}_5$ to the subset: $\{\Phi^{(4)}_{r,s}\Phi^{(5)}_{s,q}\}$ where $\Phi^{(p)}_{r,s}$ $(1 \leq r \leq p-1, 1 \leq s \leq p)$ denotes the primary fields of the minimal model series $\mathcal{M}_p$ CFT with scaling dimensions $\Delta^{(p)}_{r,s} = \frac{[(p+1)r-ps]^2-1}{2p(p+1)}$.[15] In Sec. 3 of the Appendix, we show that we have the following correspondences:

$$\begin{aligned} \mu_1 : \cos\left(\sqrt{3\pi}\Phi_2\right) : + \sigma_1 : \cos\left(\sqrt{3\pi}\Theta_2\right) : \ &\sim \ \sigma'_{\text{TIM}} \\ \mu_1 : \cos\left(\sqrt{3\pi}\Phi_2\right) : - \sigma_1 : \cos\left(\sqrt{3\pi}\Theta_2\right) : \ &\sim \ \sigma_{\text{TIM}} \epsilon_{\mathbb{Z}_3}, \end{aligned} \tag{57}$$

σ_{TIM} and σ'_{TIM} being respectively the magnetization and subleading magnetization operators of the TIM CFT with scaling dimensions $3/40$ and $7/8$.[15] In Eq. (57), $\epsilon_{\mathbb{Z}_3}$ refers to the thermal operator of the $\mathbb{Z}_3$ Potts CFT with scaling dimension $4/5$.

With all these results, one can now express the low-energy effective Hamiltonian in terms of these new degrees of freedom:

$$
\begin{aligned}
\mathcal{H}_s &= -\frac{iv}{2}\int dx\ \left(\xi_R^2\partial_x\xi_R^2 - \xi_L^2\partial_x\xi_L^2\right) + \mathcal{H}_0^{\mathrm{TIM}} + \mathcal{H}_0^{\mathbb{Z}_3} \\
&- \ \frac{\sqrt{2}}{2a}\int dx\ \Big[\left(g_\perp + g_d\right)\mu_2\sigma^{'}_{\mathrm{TIM}} \\
&+ \ \left(-g_\perp + g_d\right)\mu_2\sigma_{\mathrm{TIM}}\epsilon_{\mathbb{Z}_3}\Big], \qquad (58)
\end{aligned}
$$

where $\mathcal{H}_0^{\mathrm{TIM}}$ and $\mathcal{H}_0^{\mathbb{Z}_3}$ respectively denote the Hamiltonians of the TIM and $\mathbb{Z}_3$ CFTs. The operator $\mu_2\sigma^{'}_{\mathrm{TIM}}$ is a strongly relevant perturbation with scaling dimension 1 which couples the Ising model associated to the Majorana fermion ξ^2 with the TIM CFT. The Ising critical point is destabilized upon switching on the disorder field μ_2, while the $\sigma^{'}_{\mathrm{TIM}}$ perturbation is known to be a massive integrable deformation of the TIM CFT for all signs of its coupling constant.[55] We deduce that a spectral gap Δ for the Ising and TIM degrees of freedom is opened as soon as the tubes are coupled. In the low-energy limit where $E \ll \Delta$, the low-energy effective Hamiltonian (58) then simplifies as

$$
\mathcal{H}_s = \mathcal{H}_0^{\mathbb{Z}_3} + A\int dx\ \left(-g_\perp + g_d\right)\epsilon_{\mathbb{Z}_3}, \qquad (59)
$$

A being a non-universal constant. This model is a massive and integrable perturbation of the $\mathbb{Z}_3$ CFT.[46] A spectral gap is thus generated, except at the fine-tuned point $g_\perp = g_d$ where the model displays a quantum critical behavior in the $\mathbb{Z}_3$ Potts universality class. The position of the critical point, i.e. $g_\perp = g_d$, corresponds to the self-duality symmetry of model (55): $\Phi_{1,2} \leftrightarrow \Theta_{1,2}$.

Adding the contribution of the gapless boson Φ_0, we deduce that the quantum phase transition of the triple-tube system is governed by the SU(2)$_3$ CFT with central charge $c = 1 + 4/5 = 9/5$; this is in full agreement with the general analysis of Sec. II.

As in the $N = 2$ case, the marginal forward-scattering operator $\mathcal{O}_{\mathrm{fs}} = \partial_x\varphi_2(\partial_x\varphi_1 + \partial_x\varphi_3)$ is expected to introduce anisotropies and the symmetry of the quantum critical point is U(1) $\times$ $\mathbb{Z}_3$. In particular, using the new basis (53), we find that

$$
\mathcal{O}_{\mathrm{fs}} = \frac{2}{3}\left[(\partial_x\Phi_0)^2 - (\partial_x\Phi_2)^2\right] - \frac{2}{3\sqrt{2}}\partial_x\Phi_0\partial_x\Phi_2. \qquad (60)
$$

As expected, the first term of this equation merely introduces velocity anisotropies and different Luttinger parameters for the bosons $\Phi_{0,1,2}$ as in the double-tube case. On the other hand, the last term gives a residual coupling between the gapless boson Φ_0 and the remaining degrees of freedom. Such term has also be encountered in the analysis of the zero-temperature phase diagram of 1D three-component cold fermions; its main effect is not clear.[42] However, we think that the latter perturbation will not destroy the quantum criticality of the phase transition of the triple-tube model.

In any case, one can eliminate this term by considering a triple-tube system with transverse periodic boundary conditions as depicted in Fig. 3(b). In that case, the forward-scattering perturbation of this problem is:

$$
\begin{aligned}
\mathcal{O}_{\mathrm{fs}}^{\Delta} &= \partial_x\varphi_2(\partial_x\varphi_1 + \partial_x\varphi_3) + \partial_x\varphi_1\partial_x\varphi_3 \\
&= (\partial_x\Phi_0)^2 - \frac{1}{2}\left[(\partial_x\Phi_1)^2 + (\partial_x\Phi_2)^2\right], \qquad (61)
\end{aligned}
$$

so that this contribution is exhausted by velocities and Luttinger parameters renormalization. At the self-dual point $g_\perp = g_d$, the effective Hamiltonian which controls the transition of the model has a similar structure as in the open boundary case (see Eq. (58)):

$$
\begin{aligned}
\mathcal{H}_s^{\Delta} &= -\frac{iv}{2}\int dx\ \left(\xi_R^2\partial_x\xi_R^2 - \xi_L^2\partial_x\xi_L^2\right) + \mathcal{H}_0^{\mathrm{TIM}} + \mathcal{H}_0^{\mathbb{Z}_3} \\
&- \frac{\sqrt{2}g_d}{a}\int dx\ \mu_2\sigma^{'}_{\mathrm{TIM}} - \frac{2\pi g_d}{a}\int dx\ i\xi_R^2\xi_L^2. \qquad (62)
\end{aligned}
$$

We observe that here, the spectral gap for the Ising and TIM degrees of freedom is now explicit, due to the mass term ($m_2 = 2\pi g_d/a$) for the Majorana fermion ξ^2. Indeed, since this mass is positive, the corresponding Ising model belongs to its disordered phase with $\langle\mu_2\rangle \neq 0$. Averaging out these degrees of freedom, one is left with a TIM CFT perturbed by the subleading magnetization operator $\sigma^{'}_{\mathrm{TIM}}$, which gives a spectral gap.[55] We conclude, as in the open case, that at low-energy, the $\mathbb{Z}_3$ degrees of freedom remain untouched and display quantum criticality with central charge $c = 4/5$.

Our approach allows us to determine the leading asymptotics of the correlation functions at the quantum critical point with U(1) $\times$ $\mathbb{Z}_3$ symmetry. The bosonic creation operators $\Psi_n^\dagger$ can be expressed in terms of the bosons (53) with $K = 1/2$:

$$
\begin{aligned}
\Psi_{1,3}^\dagger &\sim e^{i\sqrt{\pi/3K_0}\,\Theta_0}e^{\pm i\sqrt{\pi}\,\Theta_1}e^{i\sqrt{\pi/3}\,\Theta_2} \\
\Psi_2^\dagger &\sim e^{i\sqrt{\pi/3K_0}\,\Theta_0}e^{i\sqrt{4\pi/3}\,\Theta_2}, \qquad (63)
\end{aligned}
$$

with $K_0 \simeq 1/2$. Using Eq. (49) and taking into account that the Ising model with disorder parameter μ_2 sits in its disordered phase, we have

$$
\begin{aligned}
\Psi_{1,3}^\dagger &\sim e^{i\sqrt{\pi/3K_0}\,\Theta_0}\sigma_1 e^{i\sqrt{\pi/3}\,\Theta_2} \\
\Psi_2^\dagger &\sim e^{i\sqrt{\pi/3K_0}\,\Theta_0}e^{i\sqrt{4\pi/3}\,\Theta_2}. \qquad (64)
\end{aligned}
$$

The next step is to express the operators $\sigma_1 e^{i\sqrt{\pi/3}\,\Theta_2}$ and $e^{i\sqrt{4\pi/3}\,\Theta_2}$, with respectively scaling dimensions $5/24$ and $1/3$, in terms of the TIM $\times$ $\mathbb{Z}_3$ degrees of freedom. We find the following identification:

$$
\begin{aligned}
\sigma_1 e^{i\sqrt{\pi/3}\,\Theta_2} &\sim \sigma_{\mathrm{TIM}}\sigma_{\mathbb{Z}_3} \\
e^{i\sqrt{4\pi/3}\,\Theta_2} &\sim \epsilon_{\mathrm{TIM}}\sigma_{\mathbb{Z}_3}, \qquad (65)
\end{aligned}
$$

$\sigma_{\mathbb{Z}_3}$ being the $\mathbb{Z}_3$ spin operator with scaling dimension $2/15$, and ϵ_{TIM}, the thermal operator of the TIM CFT with scaling dimension $1/5$. Finally, at low-energy, i.e. for energies smaller than the spectral gap of the TIM degrees of freedom, the bosonic creation operators $\Psi_n^\dagger$ of the triple-tube system simplify as follows:

$$\Psi_n^\dagger \;\sim\; e^{i\sqrt{\pi/3K_0}\;\Theta_0}\sigma_{\mathbb{Z}_3}. \tag{66}$$

We observe that $\Psi_n^\dagger$ expresses directly in terms the $\mathbb{Z}_3$ spin operator in full agreement with the identification (35) in the general case. Similarly, we can find the low-energy representation of the $2\pi\rho_0$ CDW on each tube $\rho_n^{2\pi\rho_0}$ at $K = 1/2$:

$$\begin{aligned} \rho_n^{2\pi\rho_0} \;&\sim\; e^{i2\pi\rho_0 x+\sqrt{4\pi K}\;\varphi_n} \\ &\sim\; e^{i2\pi\rho_0 x+i\sqrt{4\pi K_0/3}\;\Phi_0}\mu_{\mathbb{Z}_3}, \end{aligned} \tag{67}$$

with $K_0 \simeq 1/2$ and $\mu_{\mathbb{Z}_3}$ is the $\mathbb{Z}_3$ disorder spin operator which is dual to the $\mathbb{Z}_3$ spin operator $\sigma_{\mathbb{Z}_3}$. Using the results (66, 67), we deduce the leading asymptotics of the equal-time correlations at the quantum critical point of the triple-tube model:

$$\begin{aligned} \langle \Psi_n^\dagger(x)\,\Psi_m(0)\rangle \;&\sim\; x^{-1/(6K_0)-4/15} \\ \langle \rho_n(x)\,\rho_m(0)\rangle \;&\sim\; \rho_0^2 - \frac{K_0}{6\pi^2 x^2} + A\frac{\cos\left(2\pi\rho_0 x\right)}{x^{2K_0/3+4/15}}, \end{aligned} \tag{68}$$

with $K_0 \simeq 1/2$. The quantum phase transition is thus described by a U(1) $\times$ $\mathbb{Z}_3$ CFT with central charge $c = 1{+}4/5 = 9/5$.

B. Stability of the quantum critical point and the $\mathbb{Z}_3$ chiral clock model

The next step of the approach is to investigate the stability of this quantum critical point to generic perturbations allowed by the symmetries of the model. This includes all irrelevant perturbations, that we have neglected in the continuum description, which may change their status at the new U(1) $\times$ $\mathbb{Z}_3$ fixed point. The entire content of the $\mathbb{Z}_3$ Potts model is known[15] and the thermal operator $\epsilon_{\mathbb{Z}_3}$ is the only relevant operator having zero conformal spin and preserving the global $\mathbb{Z}_3$ symmetry of the model. The presence of two independent coupling constants in the model, namely $J_\perp$ and C_{dd}, should be enough to kill this relevant operator and reach the $\mathbb{Z}_3$ critical point. The other relevant operators of the $\mathbb{Z}_3$ Potts model carry a non-zero conformal spin: $\Phi_{(2/5,7/5)}$ and $\Phi_{(7/5,2/5)}$ are $\mathbb{Z}_3$ operators with scaling dimension $9/5$ and conformal spin $S = \pm 1$. These non-Lorentz invariant perturbations, if generated, might drive the system to the fixed point of the chiral three-state Potts universality class[56]; the general low-energy effective field theory of triple-tube systems, which controls the vicinity of the $\mathbb{Z}_3$ fixed point, would then read as follows:

$$\mathcal{H}_\delta^{\mathbb{Z}_3} = \mathcal{H}_0^{\mathbb{Z}_3} + \int dx\; \delta\Phi_{(2/5,7/5)} + \delta^*\Phi_{(7/5,2/5)} + \delta_g\;\epsilon_{\mathbb{Z}_3}, \tag{69}$$

where δ and $\delta_g = A\left(-g_\perp + g_d\right)$ are small coupling constants describing the departure from the $\mathbb{Z}_3$ quantum critical point. It is thus important to find out if the relevant non-scalar operators $\Phi_{(2/5,7/5)}, \Phi_{(7/5,2/5)}$ are permitted in the triple-tube systems investigated here.

In this respect, we observe that a non-zero conformal spin perturbation emerges in the continuum limit of the triple-tube system with open boundary conditions (Fig. 3(a)), when expanding the square root in the harmonic-fluid representation of the bosonic operator (10); for $K = 1/2$, it reads:

$$\mathcal{O}_{S=\pm1} = \sum_{n=1}^{2}\left(\partial_x\varphi_{n+1} + \partial_x\varphi_n\right)\cos\left(\sqrt{2\pi}\left(\vartheta_{n+1} - \vartheta_n\right)\right). \tag{70}$$

This term is a marginal perturbation with conformal spin $S = \pm1$, and it is invariant under parity, since $x \to -x$, $\varphi_n(x) \to -\varphi_n(-x)$, which is indeed a symmetry of Eqs. (9,10). In the triple-tube model with periodic boundary conditions (Fig. 3(b)), the non-Lorentz invariant perturbation becomes:

$$\mathcal{O}^\Delta_{S=\pm1} = \sum_{n=1}^{3}\left(\partial_x\varphi_{n+1} + \partial_x\varphi_n\right)\cos\left(\sqrt{2\pi}\left(\vartheta_{n+1} - \vartheta_n\right)\right). \tag{71}$$

Using the basis (53) and the refermionization (46, 49), we focus on the following combinations for each triple-tube system:

$$\begin{aligned} \mathcal{O}^{(1)}_{S=\pm1} \;&=\; \frac{1}{\sqrt{2}}\mu_2\sigma_1 : \partial_x\Phi_2\cos\left(\sqrt{3\pi}\Theta_2\right) : \\ \mathcal{O}^{\Delta}_{S=\pm1} \;&=\; \mathcal{O}^{(1)}_{S=\pm1} + \partial_x\Phi_2 i\pi\xi_R^1\xi_L^1, \end{aligned} \tag{72}$$

where the second operator occurs for the triple-tube model with periodic boundary conditions. We can now express these non-Lorentz invariant perturbations in terms of the TIM $\times$ $\mathbb{Z}_3$ degrees of freedom. We find the following identification up to some unimportant normalization factors:

$$\begin{aligned} \mathcal{O}^{(1)}_{S=\pm1} \;&\sim\; \mu_2\sigma_{\text{TIM}}\left[\Phi_{(2/5,7/5)} + \Phi_{(7/5,2/5)}\right] \\ \partial_x\Phi_2 i\xi_R^1\xi_L^1 \;&\sim\; \epsilon_{\text{TIM}}\left[\Phi_{(2/5,7/5)} + \Phi_{(7/5,2/5)}\right]. \end{aligned} \tag{73}$$

Thus, at energies much smaller the spectral gap of the Ising and TIM degrees of freedom, the physical properties of triple-tube systems are governed by the effective Hamiltonian (69) with $\delta = \delta^*$ (and $\delta_g = A(-g_\perp + g_d)$). The latter Hamiltonian is known to describe the physical properties of the 2D uniaxial $\mathbb{Z}_3$ chiral Potts model, the so-called Ostlund-Huse model,[33] in the vicinity of the three-state Potts critical point.[56] Interestingly enough, the competition between superfluidity and CDW in triple-tube systems is thus similar to the domain-wall wetting transition in chiral clock model.[33,57] We note that a 1D hardcore boson chain also has physical properties described by the $\mathbb{Z}_3$ chiral Potts model.[58]

The Ostlund-Huse model on the square lattice is defined as follows:

$$\begin{aligned} \mathcal{H}_{\text{OH}} \;&=\; -J\sum_{<i,j>}\cos\left[\frac{2\pi}{3}\left(n_i - n_j + \Delta\right)\right] \\ &-\; J\sum_{<i,k>}\cos\left[\frac{2\pi}{3}\left(n_i - n_k\right)\right], \end{aligned} \tag{74}$$

where a variable $n_i = 0, 1, 2$ is associated with each site i of a square lattice and the sum $< i, j >$ (respectively $< i, k >$)

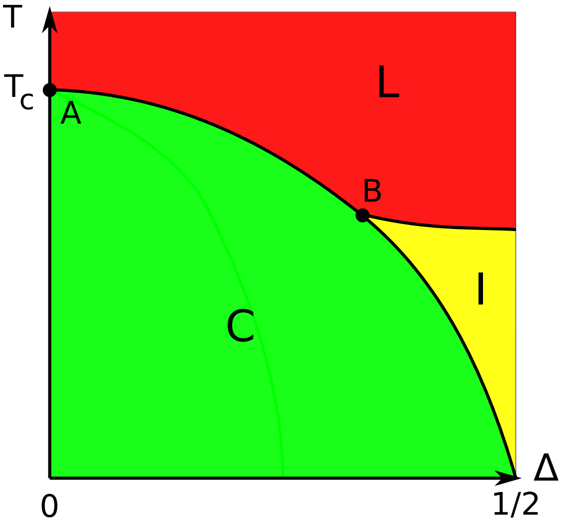

FIG. 4: (color online) Schematic phase diagram of the 2D $\mathbb{Z}_3$ chiral clock model; C, L, and I denote respectively the commensurate, liquid, and incommensurate phase; T_c is the critical temperature of the three-state Potts model and Δ the asymmetry parameter.

are taken over nearest neighbours in the axial, e.g. x, (respectively y) direction. The Ostlund-Huse model displays a global $\mathbb{Z}_3$ symmetry and has been introduced to describe the commensurate-incommensurate transition observed in monolayers absorbed on rectangular substrates.[33] For $\Delta = 0$, the model reduces to the ordinary 2D $\mathbb{Z}_3$ clock model, which is equivalent to the three-state Potts model, and enjoys a S$_3$ (the permutation group of three objects) global symmetry. Such a model displays a second-order phase transition from a commensurate (or ferromagnetic) phase to a liquid (or paramagnetic) phase in the $\mathbb{Z}_3$ parafermionic universality class. The phase diagram of the model with uniaxial anisotropy $\Delta \neq 0$ has proved complicated and very controversial (see Refs.59,60 for a review). The main effect of the asymmetry parameter Δ is to introduce a new incommensurate gapless phase (the so-called floating phase, with central charge $c = 1$) between the conventional commensurate and liquid phases (see Fig. 4 for a schematic phase diagram). The floating phase is characterized by a modulated order with a wavevector which varies continuously with T and Δ. There is considerable controversy over the possible existence of the Lifshitz point (point B in Fig. 4). To the best of our knowledge, the situation is still not settled. Three different scenari are possible:

(a) There is a Lifshitz point at finite value of Δ and the Potts critical point (point A in Fig. 4) extends along the AB line of Fig. 4.[33,61,62]

(b) The Lifshitz point moves to $\Delta = 0$: there is no direct transition between the commensurate and liquid phase but an intermediate floating phase.[63–65] There are two phase transitions to reach the liquid phase from the commensurate one: first, a commensurate-incommensurate transition followed by a KT transition.

(c) There is a Lifshitz point at finite value of Δ but the AB line of Fig. 4 is a new critical line with critical exponents different from the three-state Potts universality class.[57,66]

In our triple-tube systems, the case (a) corresponds to a U(1) $\times\mathbb{Z}_3$ quantum phase transition between the CDW and superfluid phases, described by the properties (68). In the second case (b), there is no direct transition between these two phases but an intermediate incommensurate gapless phase will then emerge. Adding the contribution of the gapless boson Φ_0, this incommensurate gapless phase has central charge $c = 1 + 1 = 2$. The correlation functions (68), in this floating phase, will be non-universal and incommensurate with a wave-vector $Q \neq 2\pi\rho_0$. We expect the extent of this incommensurate phase to be tiny since $\delta = \delta^*$ is small in our approach. Finally, in the last case (c), we still have a direct quantum phase transition between the CDW and superfluid phases. The correlations functions, at the quantum critical point, are still described by Eqs. (68) but with different (unknown) universal exponents.

Unfortunately, the low-energy properties of the effective field theory (69) with $\delta = \delta^*$ and $\delta_g = 0$ are not known and cannot help to resolve the controversy.[56] However, on general grounds, a relevant $S = \pm 1$ conformal spin perturbation usually gives rise to some incommensurate behavior.[56,67–69] The second case, i.e., the existence of an intermediate incommensurate gapless phase, is thus maybe the most probable. In addition, we expect a different behavior between the two triple-tube systems of Fig. 3 since they do not share the same symmetry. In the equilateral triangle situation, we have a lattice global S$_3$ invariance in contrast to the open case (Fig. 3(a)). Since the Ostlund-Huse model (74) does not have this invariance except at $\Delta = 0$, it is natural to conjecture that $\delta = \delta^* = 0$ in the low-energy effective Hamiltonian (69) for the periodic case. In that case, the quantum phase transition between the superfluid and CDW phases belongs to the U(1) $\times\mathbb{Z}_3$ universality class. Unfortunately, within our approach, we cannot directly check that $\delta = \delta^* = 0$. Indeed, the evaluation of these coupling constants requires the exact knowledge of the non-universal amplitudes on Ising and TIM degrees of freedom in Eq. (73) for the theory (62). In this respect, it would be very interesting in the future, to numerically investigate the zero-temperature phase diagram of lattice triple-tube models of Fig. 3. In particular, it would further shed light on the nature of the quantum phase transition and its relation to the physics of the 2D $\mathbb{Z}_3$ chiral Potts model.

V. CONCLUDING REMARKS

In summary, we have investigated the low-energy properties of a system of N 1D dipolar bosons tubes coupled together via intertube hopping and dipole-dipole interactions. Here, we have focused our analysis on the quantum-phase transition for incommensurate filling that reflects the competition between the two different coupling mechanisms using a phenomenological bosonization approach. The transition separates a superfluid phase from a CDW phase when the Luttinger parameter of the bosons fields is $K = 1/2$. This value can be reached here thanks to the long-range nature of the dipole-dipole interaction. In stark contrast to a single-tube case where the transition is a simple cross-over, the main effect of coupling the 1D tubes through hopping and density interactions is to give rise to a genuine quantum-phase transition.

Using the powerful machinery of the CFT approach, we have determined the main long-wavelength properties of this transition which turns out to be very exotic. In particular, we have revealed that the quantum phase transition is described by the SU(2)$_N$ CFT, or equivalently to the U(1) $\times$ $\mathbb{Z}_N$ CFT, with a fractional central charge $c = 3N/(N+2)$. The $\mathbb{Z}_N$ critical degrees of freedom are highly nontrivial and nonlocal with respect to the original atoms or polar molecules of the model. The quantum critical point can be attained by a fine-tuning of the coupling constants that seem reasonably realistic in the context of cold polar molecules. In this respect, this work opens the possibility to investigate the exotic physics of $\mathbb{Z}_N$ parafermions in the context of ultracold quantum bosonic gases.

In the $N = 2$ case, we have investigated in details the main characteristics of the quantum critical point which was shown to belong to the SU(2)$_2$ universality class with central charge $c = 3/2$. The triple-tube case ($N = 3$) is particularly promising since the quantum phase transition is governed by U(1)$\times\mathbb{Z}_3$ degrees of freedom. In particular, within our low-energy approach, we have connected this problem to the physics of the 2D $\mathbb{Z}_3$ chiral Potts model. In this respect, it will be important to carry out a thorough large-scale numerical analysis for mapping out the zero-temperature phase diagram of the triple-tube systems by adding an optical lattice in the x-direction. The commensurate case is also interesting and will be investigated elsewhere. We hope that ongoing experimental research on polar molecules will allow to probe the quantum phase transition discussed in this paper.

Acknowledgements

We would like to thank A. A. Nersesyan for encouragement and his interest in the work.

Appendix A: Free-field representations

In this Appendix, we present some important technical details on the SU(2)$_N$ quantum critical properties of the effective Hamiltonian (25), which controls the quantum phase transition of the coupled tubes system.

1. Free-field representation of SU(2)$_N$ CFT

As stated in Sec. II B, for $g_\perp = g_d$ and $K = 1/2$, the Hamiltonian is given by Eq. (28) and displays an enlarged SU(2)$_L$ $\times$ SU(2)$_R$ global symmetry. Let us consider its non-interacting part $\mathcal{H}_0^*$, where "$*$" denotes the $g_\perp = g_d$ point. Each boson φ_n describes an SU(2)$_1$ CFT with central charge $c = 1$, generated by the left and right SU(2)$_1$ current:

$$\begin{aligned} j^\dagger_{nR,L} &= \frac{1}{2\pi} : \exp(\mp i\sqrt{8\pi}\, \varphi_{nR,L}) : \\ j^z_{nR,L} &= \frac{1}{\sqrt{2\pi}} \partial_x \varphi_{nR,L}, \end{aligned} \tag{A1}$$

where $: A :$ is the standard normal ordering of a bosonic operator A. In this work, the chiral bosonic fields $\varphi_{nR(L)}$ are defined as:

$$\begin{aligned} \varphi_n &= \varphi_{nL} + \varphi_{nR}, \\ \vartheta_n &= \varphi_{nL} - \varphi_{nR}, \end{aligned} \tag{A2}$$

and we are working with the prescription: $[\varphi_{nR}, \varphi_{mL}] = i\delta_{nm}/4$. The bosonic fields are normalized by the following operator product expansion (OPE):

$$\begin{aligned} \varphi_{nL}(z)\varphi_{mL}(\omega) &\sim -\frac{\delta_{nm}}{4\pi} \ln(z-\omega), \\ \varphi_{nR}(\bar z)\varphi_{mR}(\bar\omega) &\sim -\frac{\delta_{nm}}{4\pi} \ln(\bar z - \bar\omega), \end{aligned} \tag{A3}$$

with $z = v\tau + ix$, $\bar z = v\tau - ix$, and τ is the imaginary time.

Eqs. (A1) give a free-boson representation of the SU(2)$_1$ currents that satisfy the so-called SU(2)$_1$ Kac-Moody algebra defined by the OPE:[15]

$$j^\alpha_{nL}(z)\, j^\beta_{nL}(\omega) \sim \frac{\delta^{\alpha\beta}}{8\pi^2(z-\omega)^2} + \frac{i\epsilon^{\alpha\beta\gamma} j^\gamma_{nL}(\omega)}{2\pi(z-\omega)}, \tag{A4}$$

with $\alpha, \beta, \gamma = x, y, z$ and a similar result for the right current. Indeed, using Eq. (A3) and OPEs involving vertex operators:[15]

$$\begin{aligned} &: e^{ia\varphi_{nL}} : (z) : e^{ib\varphi_{nL}} : (\omega) \\ &\qquad \sim (z-\omega)^{ab/4\pi} : e^{ia\varphi_{nL}(z) + ib\varphi_{nL}(\omega)} :, \\ &\partial_x \varphi_{nL}(z) : e^{ia\varphi_{nL}} : (\omega) \sim \frac{a}{4\pi(z-\omega)} : e^{ia\varphi_{nL}} : (\omega), \end{aligned} \tag{A5}$$

one shows that:

$$\begin{aligned} j^\pm_{nL}(z) j^\mp_{nL}(\omega) &\sim \frac{1}{4\pi^2(z-\omega)^2} : e^{\pm i\sqrt{8\pi}(\varphi_{nL}(z) - \varphi_{nL}(\omega))} :, \\ &\sim \frac{1}{4\pi^2(z-\omega)^2} \pm \frac{1}{\pi(z-\omega)} j^z_{nL}(\omega), \\ j^\pm_{nL}(z) j^z_{nL}(\omega) &\sim \frac{1}{2\pi\sqrt{2\pi}} \frac{\mp\sqrt{8\pi}}{4\pi(z-\omega)} : e^{\pm i\sqrt{8\pi}\varphi_{nL}} : (\omega), \\ &\sim \frac{\mp 1}{2\pi(z-\omega)} j^\pm_{nL}(\omega), \\ j^z_{nL}(z) j^z_{nL}(\omega) &\sim \frac{1}{8\pi^2(z-\omega)^2}. \end{aligned} \tag{A6}$$

This is nothing else but the algebra (A4).

As any CFT, the SU(2)$_1$ CFT described by the bosonic fields $\varphi_{nR(L)}$ possesses a stress-energy tensor. Its left – i.e. holomorphic – component is given by:

$$T_n = \frac{4\pi^2}{3} : \mathbf{j}_{nL} \cdot \mathbf{j}_{nL} :, \tag{A7}$$

and satisfies the defining relation of a stress-energy tensor of a CFT:[15]

$$T(z)T(\omega) \sim \frac{c/2}{(z-\omega)^4} + \frac{2T(\omega)}{(z-\omega)^2} + \frac{\partial T(\omega)}{z-\omega}, \qquad \text{(A8)}$$

where $\partial = \partial/\partial z$, and c is the central charge for the CFT in question; for the SU(2)$_1$ CFT, $c = 1$ as already mentioned before. Using the representation (A1), the SU(2)$_1$ stress-energy tensor can be directly expressed in terms of the boson field:

$$T_n = 2\pi : (\partial_x \varphi_{nL})^2 :; \qquad \text{(A9)}$$

it is straightforward to check that the definition (A8) is indeed reproduced.

The non-interacting part of the Hamiltonian (28), $\mathcal{H}_0^*$, can be written in terms of the N SU(2)$_1$ currents (A1):

$$\mathcal{H}_0^* = \sum_{n=1}^{N} \int dx \, \frac{2\pi v}{3} \left(: \mathbf{j}_{nL} \cdot \mathbf{j}_{nL} : + : \mathbf{j}_{nR} \cdot \mathbf{j}_{nR} : \right), \qquad \text{(A10)}$$

and its underlying CFT is thus SU(2)$_1 \times$SU(2)$_1 \times \cdots \times$ SU(2)$_1$ with central charge N. If we now combine the N SU(2)$_1$ currents together:

$$\begin{aligned} I^{\dagger}_{R,L} &= \frac{1}{2\pi} \sum_{n=1}^{N} : \exp(\mp i \sqrt{8\pi} \varphi_{nR,L}) :, \\ I^{z}_{R,L} &= \frac{1}{\sqrt{2\pi}} \sum_{n=1}^{N} \partial_x \varphi_{nR,L}, \end{aligned} \qquad \text{(A11)}$$

the resulting object is an SU(2)$_N$ current. Indeed, one can show, similarly to the SU(2)$_1$ case, that it satisfies the SU(2)$_N$ Kac-Moody algebra:

$$I_L^{\alpha}(z) \, I_L^{\beta}(\omega) \sim \frac{N \delta^{\alpha\beta}}{8\pi^2 (z-\omega)^2} + \frac{i \epsilon^{\alpha\beta\gamma} I_L^{\gamma}(\omega)}{2\pi (z-\omega)}. \qquad \text{(A12)}$$

The holomorphic part of the stress-energy tensor of the SU(2)$_N$ CFT is defined by:

$$T_{\text{SU(2)}_N} = \frac{4\pi^2}{N+2} : \mathbf{I}_L \cdot \mathbf{I}_L : . \qquad \text{(A13)}$$

It satisfies the relation (A8) with a central charge $c_{\text{SU(2)}_N} = 3N/(N+2)$. Using the identification (A11), we find a free-field representation of the SU(2)$_N$ stress-energy tensor in terms of the bosonic fields φ_{nL}:

$$\begin{aligned} T_{\text{SU(2)}_N} &= \frac{6\pi}{N+2} \sum_{n=1}^{N} : (\partial_x \varphi_{nL})^2 : \\ &+ \frac{1}{N+2} \sum_{n \neq m = 1}^{N} : \cos\left[\sqrt{8\pi}(\varphi_{nL} - \varphi_{mL})\right] : \\ &+ \frac{2\pi}{N+2} \sum_{n \neq m = 1}^{N} : \partial_x \varphi_{nL} \partial_x \varphi_{mL} : . \end{aligned} \qquad \text{(A14)}$$

2. Self-dual perturbation and $\mathcal{G}_N$ primary field

In Sec. II C, in order to investigate the critical properties of the model, we have introduced the $\mathcal{G}_N$ CFT through the conformal embedding (31):

$$\text{SU(2)}_1 \times \text{SU(2)}_1 \times \cdots \times \text{SU(2)}_1 \to \text{SU(2)}_N \times \mathcal{G}_N. \qquad \text{(A15)}$$

Its stress-energy tensor is the difference between the N SU(2)$_1$ and the SU(2)$_N$ stress-energy tensors, i.e., in the bosonic description:

$$\begin{aligned} T_{\mathcal{G}_N} &= \left(\sum_{n=1}^{N} T_n \right) - T_{SU(2)_N} \qquad \text{(A16)} \\ &= \frac{2\pi(N-1)}{N+2} \sum_n : (\partial_x \varphi_{nL})^2 : \\ &- \frac{1}{N+2} \sum_{n \neq m} : \cos\left(\sqrt{8\pi}(\varphi_{nL} - \varphi_{mL})\right) : \\ &- \frac{2\pi}{N+2} \sum_{n \neq m} : \partial_x \varphi_{nL} \partial_x \varphi_{mL} : . \qquad \text{(A17)} \end{aligned}$$

Let us show that indeed $T_{\mathcal{G}_N}$ satisfies the OPE of stress-energy tensors (A8) with a central charge $c_{\text{G}_N} = N(N-1)/(N+2)$. Since we already know the OPE that T_n and $T_{SU(2)_N}$ satisfy (see Eq. (A8)), we only need to compute the OPE between the N SU(2)$_1$ and the SU(2)$_N$ stress-energy tensors. Using the free-field representations (A14, A17) and Eq. (A5), one obtains:

$$\begin{aligned} T_{\text{SU(2)}_N}(z) \sum_{n=1}^{N} T_n(\omega) &\sim \frac{3N}{2(N+2)} \frac{1}{(z-\omega)^4} + \frac{2T_{\text{SU(2)}_N}(\omega)}{(z-\omega)^2} \\ &+ \frac{\partial T_{\text{SU(2)}_N}(\omega)}{z-\omega}. \end{aligned} \qquad \text{(A18)}$$

The OPE $\sum_{n=1}^{N} T_n(z) T_{\text{SU(2)}_N}(\omega)$ can be easily deduced from the former by exchanging z and ω, then performing an expansion of z around ω; it has the exact same form. Combining all these OPEs together, we finally have:

$$\begin{aligned} & T_{\mathcal{G}_N}(z) T_{\mathcal{G}_N}(\omega) \\ &= \sum_{n,m=1}^{N} T_n(z) T_m(\omega) + T_{SU(2)_N}(z) T_{SU(2)_N}(\omega) \\ &\quad - T_{\text{SU(2)}_N}(z) \sum_{n=1}^{N} T_n(\omega) - \sum_{n=1}^{N} T_n(z) T_{\text{SU(2)}_N}(\omega) \\ &\sim \frac{N(N-1)}{2(N+2) z^4} + \frac{2T_{\mathcal{G}_N}(\omega)}{(z-\omega)^2} + \frac{\partial T_{\mathcal{G}_N}(\omega)}{z-\omega}, \end{aligned} \qquad \text{(A19)}$$

which proves the value of the central charge $c_{\text{G}_N} = N(N-1)/(N+2)$ asserted above.

In the analysis of Sec. II C, we have used some crucial properties of the self-dual term (33) that is responsible for the quantum phase transition in the dipolar bosons tubes. With the definitions above at hand, we now demonstrate these properties. In terms of the bosonic fields, the self-dual term reads:

$$\begin{aligned}\mathcal{V}_{\rm sd} &= \sum_{i=1}^{N-1} :\cos(\sqrt{2\pi}(\varphi_{i+1}-\varphi_i)): \\ &\quad + :\cos(\sqrt{2\pi}(\vartheta_{i+1}-\vartheta_i)): . \end{aligned} \tag{A20}$$

Let us check explicitely that it is a singlet under the $\mathrm{SU}(2)_N$ CFT:

$$\vec{I}_L(z)\mathcal{V}_{\rm sd}(\omega,\bar\omega) \sim \vec{0}, \tag{A21}$$

and similarly for the right component. First of all, we have, using Eq. (A5):

$$\begin{aligned}& I_L^x(z) :\cos\sqrt{2\pi}(\varphi_{k+1}-\varphi_k):(\omega,\bar\omega) \\ &\sim \frac{1}{4\pi}\sum_i \frac{-i}{(z-\omega)}\Big(\delta^{i,k+1}[\widetilde{C}_{k+1}C_k - \widetilde{S}_{k+1}S_k] \\ &\qquad +\delta^{i,k}[C_{k+1}\widetilde{C}_k - S_{k+1}\widetilde{S}_k]\Big)(\omega,\bar\omega), \\ &\sim \frac{-i}{4\pi(z-\omega)}\Big(\widetilde{C}_{k+1}C_k - \widetilde{S}_{k+1}S_k \\ &+C_{k+1}\widetilde{C}_k - S_{k+1}\widetilde{S}_k\Big)(\omega,\bar\omega), \\ & I_L^x(z) :\cos(\sqrt{2\pi}(\vartheta_{k+1}-\vartheta_k)):(\omega,\bar\omega) \\ &\sim \frac{i}{4\pi(z-\omega)}\Big(C_{k+1}\widetilde{C}_k - S_{k+1}\widetilde{S}_k \\ &+\widetilde{C}_{k+1}C_k - \widetilde{S}_{k+1}S_k\Big)(\omega,\bar\omega), \end{aligned} \tag{A22}$$

where we have adopted the shorthand notation:

$$:\cos(\sqrt{2\pi}\varphi_k) := C_k, \qquad :\cos(\sqrt{2\pi}\vartheta_k) := \widetilde{C}_k, \tag{A23}$$

and with similar definitions for the sine functions S_k and $\widetilde{S}_k$. We conclude thus: $I_L{}^x(z)\mathcal{V}_{\rm sd}(\omega,\bar\omega)\sim 0$, and similarly for the y component of the $\mathrm{SU}(2)_N$ current I_L^y. For the z component, we have, using Eq. (A5):

$$\begin{aligned}& I_L{}^z(z) :\cos\sqrt{2\pi}(\varphi_{k+1}-\varphi_k):(\omega,\bar\omega) \\ &\sim \frac{i}{4\pi}\sum_i \frac{1}{z-\omega}\Big(\delta^{i,k+1} :\sin\sqrt{2\pi}(\varphi_{k+1}-\varphi_k): \\ &\qquad -\delta^{i,k} :\sin\sqrt{2\pi}(\varphi_{k+1}-\varphi_k):\Big)(\omega,\bar\omega) \\ &\sim 0. \end{aligned} \tag{A24}$$

The same also applies for the second term of $\mathcal{V}_{\rm sd}$ and that finally proves Eq. (A21).

The second important property is that $\mathcal{V}_{\rm sd}$ is a primary field under the $\mathcal{G}_N$ CFT, with scaling dimension $\Delta_{\mathcal{V}}=1$:

$$T_{\mathcal{G}_N}(z)\mathcal{V}_{\rm sd}(\omega,\bar\omega) \sim \frac{\mathcal{V}_{\rm sd}(\omega,\bar\omega)}{2(z-\omega)^2} + \frac{\partial\mathcal{V}_{\rm sd}(\omega,\bar\omega)}{z-\omega}. \tag{A25}$$

Let us check that $\mathcal{V}_{\rm sd}$ displays such property. First, we have just shown that $\overrightarrow{I_L}(z)\mathcal{V}_{\rm sd}(\omega,\bar\omega)\sim 0$, so it is straightforward to see that $T_{\mathrm{SU}(2)_N}(z)\mathcal{V}_{\rm sd}(\omega,\bar\omega)\sim 0$. We are left with the OPE of the N $\mathrm{SU}(2)_1$ stress-energy tensors with $\mathcal{V}_{\rm sd}$:

$$\begin{aligned}& \sum_{n=1}^N T_n(z) :\cos[\sqrt{2\pi}(\varphi_k-\varphi_{k+1})]:(\omega,\bar\omega) \\ &\sim \sum_{n=1}^N \frac{1}{4}\frac{1}{(z-\omega)^2}\left(\delta_{n,k}+\delta_{n,k+1}\right) \\ &\qquad \times :[C_kC_{k+1}+S_kS_{k+1}]:(\omega,\bar\omega) \\ &+\sum_{n=1}^N \frac{1}{z-\omega}\Big\{\delta_{n,k}\left[\partial(C_k)C_{k+1}+\partial(S_k)S_{k+1}\right] \\ &\qquad +\delta_{n,k+1}\left[C_k\partial(C_{k+1})+S_k\partial(S_{k+1})\right]\Big\}(\omega,\bar\omega), \\ &\sim \frac{1}{2}\frac{1}{(z-\omega)^2} :\cos\left[\sqrt{2\pi}(\varphi_k-\varphi_{k+1})\right]:(\omega,\bar\omega) \\ &\qquad +\frac{1}{z-\omega}\partial\left(:\cos\left[\sqrt{2\pi}(\varphi_k-\varphi_{k+1})\right]:\right)(\omega,\bar\omega), \end{aligned} \tag{A26}$$

and similarly for the second term of $\mathcal{V}_{\rm sd}$, which proves finally Eq. (A25).

3. Free-field representation of the TIM and $\mathbb{Z}_3$ Potts CFTs

In this section, we give a proof of the non-trivial identification (57) which occurs in triple-tube systems.

It is first important to observe that the free massless bosonic field Φ_2 has a very special compactification radius $R_2 = \sqrt{3/\pi}$ in the classification of the CFT with central charge $c=1$. At this radius, it displays a CFT with an extended symmetry: a $N=2$ (respectively $N=1$) superconformal field theory (SCFT) when the bosonic field Φ_2 is compactified along a circle (respectively an orbifold $\Phi_2\sim-\Phi_2$) with radius R_2.[70] Forgetting the contribution of the Majorana fermion ξ_L^2, the conformal symmetry of the non-interacting limit of model (56) is Ising × [$c=1$ SCFT], with central charge $c=3/2$. The latter CFT can also be described in terms of the product of TIM × $\mathbb{Z}_3$ Potts CFTs with central charge $c=7/10+4/5=3/2$. The precise conformal embedding has been derived by the authors of Ref.45:

$$\mathbb{Z}_2\times(c=1\ N=1\ \mathrm{SCFT}) = P\left[\mathcal{M}_4\times\mathcal{M}_5\right], \tag{A27}$$

where the projection P restricts the primary operators of $\mathcal{M}_4\times\mathcal{M}_5$ to the subset: $\{\Phi^{(4)}_{r,s}\Phi^{(5)}_{s,q}\}$, $\Phi^{(p)}_{r,s}$ ($1\le r\le p-1, 1\le s\le p$) being the primary operator of $\mathcal{M}_p$ CFT.

As is well-known, the (left) stress-energy tensor of the $\mathbb{Z}_2$ (or Ising) CFT expresses directly in terms of the Majorana fermion ξ_L^1: $T_I=-\pi:\xi_L^1\partial\xi_L^1:$. It is indeed straightforward to check that T_I satisfies the defining relation (A8) of a stress-energy tensor with $c=1/2$. The left Majorana ξ_L^1 is a primary field with holomorphic weight $h = 1/2$:

$$\begin{aligned} T_I\left(z\right)\xi_L^1\left(0\right) &\sim \frac{\xi_L^1\left(0\right)}{2z^2} + \frac{\partial\xi_L^1\left(0\right)}{z} \\ \xi_L^1\left(z\right)\xi_L^1\left(0\right) &\sim \frac{1}{2\pi z} + \frac{z}{\pi}T_I\left(0\right) + \frac{z^2}{2\pi}\partial T_I\left(0\right). \end{aligned} \tag{A28}$$

For the $N = 1$ SCFT with central charge $c = 1$, the stress-energy tensor is simply given by Eq. (A9): $T_0 = -2\pi : (\partial\Phi_{2L})^2 :$. On top of this bosonic tensor, the $N = 1$ SCFT is characterized by the existence of a fermionic current G with holomorphic weight $h = 3/2$:[71]

$$\begin{aligned} T_0\left(z\right)G\left(0\right) &\sim \frac{3G\left(0\right)}{2z^2} + \frac{\partial G\left(0\right)}{z} \\ G\left(z\right)G\left(0\right) &\sim \frac{1}{z^3} + \frac{3T_0\left(0\right)}{z} + \frac{3\partial T_0\left(0\right)}{2}. \end{aligned} \tag{A29}$$

In the particular case of the $N = 1$ SCFT with central charge $c = 1$, the current G has a simple free-field representation in terms of the free-massless boson Φ_{2L}:[70]

$$G = \sqrt{2} : \cos(\sqrt{12\pi}\Phi_{2L}) : . \tag{A30}$$

It is indeed easy to check, using Eq. (A5), that the OPEs (A29) are reproduced from this identification.

From all these definitions, we find a new free-field representation of the left stress-energy tensors of the TIM and $\mathbb{Z}_3$ Potts CFTs in terms of a Majorana fermion and a free-massless boson:

$$\begin{aligned} T_{\rm TIM} &= \frac{1}{5}T_I + \frac{3}{5}T_0 - \frac{4\sqrt{\pi}}{5}\xi_L^1 : \cos(\sqrt{12\pi}\Phi_{2L}) : \\ T_{\mathbb{Z}_3} &= \frac{4}{5}T_I + \frac{2}{5}T_0 + \frac{4\sqrt{\pi}}{5}\xi_L^1 : \cos(\sqrt{12\pi}\Phi_{2L}) :, \end{aligned} \tag{A31}$$

where $T_{\rm TIM}$ and $T_{\mathbb{Z}_3}$ denote respectively the stress-energy tensor of the TIM and $\mathbb{Z}_3$ Potts CFTs. Using the results (A28, A29), one can indeed show that $T_{\rm TIM}$ (respectively $T_{\mathbb{Z}_3}$) satisfies the definition (A8) with $c = 7/10$ (respectively $c = 4/5$), together with the decoupling: $T_{\rm TIM}(z)T_{\mathbb{Z}_3}(0) \sim 0$. In addition, we note that we have $T_{\rm TIM} + T_{\mathbb{Z}_3} = T_I + T_0$ in full agreement with the existence of the conformal embedding (A27).

We are now in position with the free-field representation (A31) to show the identification (57). In this respect, let us introduce the following operators:

$$\begin{aligned} \mathcal{O}_1 &= \mu_1 : \cos\left(\sqrt{3\pi}\Phi_2\right) : + \sigma_1 : \cos\left(\sqrt{3\pi}\Theta_2\right) : \\ \mathcal{O}_2 &= \mu_1 : \cos\left(\sqrt{3\pi}\Phi_2\right) : - \sigma_1 : \cos\left(\sqrt{3\pi}\Theta_2\right) : . \end{aligned} \tag{A32}$$

Let us first show that $\mathcal{O}_1$ is a singlet under the $\mathbb{Z}_3$ Potts CFT and a primary operator of the TIM CFT with holomorphic weight $h = 7/16$. To this end, we need the following OPEs for a massless boson field that can be obtained from Eq. (A5):

$$\begin{aligned} &: \cos(\sqrt{12\pi}\Phi_{2L}) : (z) : \cos(\sqrt{3\pi}\Phi_2) : (0,0) \sim \\ &\frac{e^{-i3\pi/4}}{2z^{3/2}}\Big[: \cos(\sqrt{3\pi}\Theta_2) : + 2z : \partial\cos(\sqrt{3\pi}\Theta_2) :\Big](0,0) \\ &: \cos(\sqrt{12\pi}\Phi_{2L}) : (z) : \cos(\sqrt{3\pi}\Theta_2) : (0,0) \sim \\ &\frac{e^{i3\pi/4}}{2z^{3/2}}\Big[: \cos(\sqrt{3\pi}\Phi_2) : + 2z : \partial\cos(\sqrt{3\pi}\Phi_2) :\Big](0,0). \end{aligned} \tag{A33}$$

The following Ising OPEs, which can be found in Ref.72, are also needed:

$$\begin{aligned} \xi_L^1\left(z\right)\sigma_1\left(0,0\right) &\sim \frac{e^{i\pi/4}}{2\sqrt{\pi}z^{1/2}}\left[\mu_1 + 4z\partial\mu_1\right](0,0) \\ \xi_L^1\left(z\right)\mu_1\left(0,0\right) &\sim \frac{e^{-i\pi/4}}{2\sqrt{\pi}z^{1/2}}\left[\sigma_1 + 4z\partial\sigma_1\right](0,0). \end{aligned} \tag{A34}$$

With all these identifications, it becomes straightforward to obtain the following result directly from Eq. (A31):

$$\begin{aligned} T_{\rm TIM}(z)\mathcal{O}_1(0,0) &\sim \frac{7\mathcal{O}_1(0,0)}{16z^2} + \frac{\partial\mathcal{O}_1(0,0)}{z} \\ T_{\mathbb{Z}_3}(z)\mathcal{O}_1(0,0) &\sim 0, \end{aligned} \tag{A35}$$

which states that $\mathcal{O}_1$ is indeed a primary operator of the TIM CFT with scaling dimension $7/8$. It is thus proportional to the subleading magnetization $\sigma'_{\rm TIM}$. Using the correlation (50), one can fix the normalization factor by evaluating the two-point function of $\mathcal{O}_1$:

$$\begin{aligned} \langle\mathcal{O}_1(z,\bar{z})\mathcal{O}_1(0,0)\rangle &\sim |z|^{-7/4} \\ &= \langle\sigma'_{\rm TIM}(z,\bar{z})\,\sigma'_{\rm TIM}(0,0)\rangle, \end{aligned} \tag{A36}$$

so that we deduce $\mathcal{O}_1 \sim \sigma'_{\rm TIM}$. Finally, from its definition (A32), it is easy to check that $\mathcal{O}_2$ is a primary operator of the $\mathcal{M}_4 \times \mathcal{M}_5$ CFT with scaling dimension $7/8$:

$$\begin{aligned} \left(T_{\rm TIM} + T_{\mathbb{Z}_3}\right)(z)\mathcal{O}_2(0,0) &= \left(T_I + T_0\right)(z)\mathcal{O}_2(0,0) \quad \text{(A37)} \\ &\sim \frac{7\mathcal{O}_2(0,0)}{16z^2} + \frac{\partial\mathcal{O}_2(0,0)}{z}. \end{aligned}$$

The $P[\mathcal{M}_4 \times \mathcal{M}_5]$ CFT contains only two primary operators with scaling dimension $7/8$, i.e., $\sigma'_{\rm TIM}$ and $\sigma_{\rm TIM}\epsilon_{\mathbb{Z}_3}$. We thus find that $\mathcal{O}_2 \sim \sigma_{\rm TIM}\epsilon_{\mathbb{Z}_3}$ since $\mathcal{O}_1 \sim \sigma'_{\rm TIM}$.
